WOHLAU, or *Wolau*, a principality of Silesia, bounded on the north by the principality of Glogau, on the east by Poland and the principality of Oels, on the south by the principalities of Breslau and Lignitz, and on the west by the principalities of Lignitz and Glogau; situated on both sides of the Oder. The soil is in some parts dry, in others marshy, or overrun with woods and bushes, though several tracts also yield good corn.

WOHRA, a river of Germany, which runs into the Werra, 2 miles N.W. of Echwegen, in the principality of Hesse.

WOHRD, a town of Bavaria, in the territory of Nuremberg, near Nuremberg.

WOINITSCH, a town of Austrian Poland; 36 miles E. of Cracow.

WOITSBACH, a town of Bohemia, in the circle of Boleslaw; 8 miles E. of Krottau.

WOITSBERG. See **VOITSBERG**.

WOKING, a town of England, in the county of Surrey; 8 miles N. of Guildford.

WOKINGHAM, or **OAKINGHAM**, a market-town and parish in the hundred of Sonning, and county of Berks, England, is situated in Windfor forest 7½ miles E.S.E. from Reading, and 32¼ W.S.W. from London. The population in 1811 was 2085 persons, inhabiting 435 houses. The market is held on Tuesday, and the fairs on the 23d of April, 11th of June, 10th of October, and 2d of November. The town, incorporated by James I., is governed by an alderman, high steward, recorder, burgeses, and a town-clerk; and at this place are held all the courts for Windfor forest. Although within the bounds of Berkshire, the church stands in an insulated part of Wiltshire: it is a large and handsome edifice. The inhabitants are chiefly employed in agriculture, throwing silk, sorting wool, and making shoes: the gauze manufacture was some years ago introduced. At Luckelygreen, near this town, is an hospital, founded in 1665 by Henry Lucas, esq. for sixteen poor men and a master: the trustees of the charity are the Drapers' company of London. About four miles S.E. from Wokingham, is a large and irregular fortification, with a double ditch, commonly called Cæsar's camp, situated on the summit of a hill. Half a mile to the southward of this camp is the Devil's ditch, a raised road nearly ninety feet wide, running east and west, with a trench on each side. In 1661 George Staverton gave the rent of a house in this place for the purpose of buying a bull, to be baited and killed at Christmas, for the benefit of the poor of Wokingham; but this being thought insufficient, the inhabitants are in the habit of purchasing another beast for the same purpose. Archbishop Laud gave a portion of certain fee-farm rents, which produces about 40*l. per annum*, to the parish. Every third year it is divided, pursuant to the donor's intention, between three poor maidens of the age of eighteen, natives of the town, and members of the church of England, who have served the same master or mistress for three years together: the other years it is appropriated to the apprenticing of poor boys. Dr. Thomas Godwin, bishop of Bath and Wells, was a native of this town, where he was born in 1517.

About four miles S. from Wokingham is Billingbear, one of the seats of lord Braybrooke. The house is a large irregular building, seated in a fine park. A particular history and description of this place is given, with a view, in Havell's *Views of Seats*, folio, 1816.—*Beauties of England and Wales*, Berkshire; by J. Britton and E. W. Brayley, London, 8vo. 1802. *Magna Britannia*, by S. and the Rev. D. Lysons, vol. 1. 4to. 1806.

WOKSCHITZ, a town of Bohemia, in the circle of Konigingratz; 2 miles W. of Gitschin.

WOLBECK, or **WALDBECK**, a town of Germany, in the bishopric of Munster; 7 miles S.S.E. of Munster. N. lat. 51° 53'. E. long. 7° 52'.

WOLBORZ, a town of the duchy of Warsaw; 41 miles S. of Siradia.

WOLCHRADITZ, a town of Moravia, in the circle of Brunn; 18 miles S.S.E. of Brunn.

WOLCKENSTEIN, a town of the duchy of Stiria; 6 miles W.N.W. of Rottenmann.

WOLCKERSDORF, a town of Germany, in the margravate of Anspach; 2 miles N. of Schwabach.—Also, a town of Austria, on the Rusbach; 8 miles E.N.E. of Korn Neuburg.

WOLCKERSHAUSEN, a town of the duchy of Wurzburg; 6 miles N. of Schweinfurt.—Also, a town of the county of Henneberg; 3 miles N. of Menungen.

WOLCOTT. See **WOOLCOTT**.

WOLCOTT, a town of Connecticut, in the county of New Haven, near Fairfield, with 952 inhabitants.

WOLD, signifies a plain, down, or open champaign ground, hilly, and void of wood.

Hence the names *Stow* in the *Wold*, and *Cotfwoold*, in Gloucester-

Gloucestershire; whence also that part of Leicestershire, which lies northward beyond the Wrekin, is called the Wold of Leicestershire.

WOLD, or *Weld*, among *Dyers*. See WELD.

WOLDEGGE, or WOLDECK, in *Geography*, a town of the duchy of Mecklenburg; 13 miles S.E. of New Brandenburg.

WOLDENBERG, a town of the New Mark of Brandenburg; 9 miles N.E. of Friedburg. N. lat. 53°. E. long. 15° 45'.

WOLEIN. See MIRZIN.

WOLESCHITZ, a town of Bohemia, in the circle of Kaurzim; 4 miles W.S.W. of Kaurzim.

WOLF, CHRISTIAN, in *Biography*, an eminent mathematician and philosopher, was born at Breslau in 1679, and well educated under able masters in different branches of literature and science. At the age of 21, he was entered at the university of Jena, which was then in high reputation; and quitting Jena in 1702, he prosecuted his studies at Leipzig, where, in the following year, he took his degree of master of arts, publishing on the occasion a dissertation, intitled "Philosophia practica Universalis Mathematico modo conscripta." In 1704 he published another dissertation, on the differential and infinitesimal calculus. Having studied theology as well as philosophy at Leipzig, he officiated as a preacher; and being invited to undertake the office of pastor in a country village, he was advised by Leibnitz to decline it, and to pursue the study of philosophy. As he commenced his literary career with great reputation, he was proposed to be an associate in the periodical work, intitled "Acta Eruditorum;" and in this connection he continued for many years, employing his leisure hours in teaching mathematics, logic, and natural philosophy. When the Swedes made an incursion into Saxony in the year 1706, he quitted Leipzig, and removed to Berlin; where a recommendatory letter of Leibnitz procured for him from Frederic I. the office of professor of mathematics at Halle. In 1709 he published, in Latin, his treatise on "Aerometry;" and in the following year his "Elements of Mathematics," in 4 vols. which have passed through several editions. Having composed a very ingenious essay on the intense cold of the ensuing winter, he was elected a member of the Royal Society of London, and soon after a member of the Academy of Sciences at Berlin. In 1711 he published his tables of sines and tangents, and in the next year his treatise on logic, in German, highly commended by Formey, and translated into Latin, French, and other languages. The first two volumes of his large work on the mathematics appeared in 1713, and these were afterwards followed by three more. By the advice of his friend Leibnitz, he refused an invitation from Peter the Great to remove from Halle to Petersburg. On the death of Leibnitz in 1726, Wolf drew up his life, which supplied Fontenelle with materials for his eulogy. In 1718 he published "Meditations on God, the World, and the Human Soul," which were reprinted in the following year. About this time the reputation of Wolf and the jealousy of his rivals occasioned a literary contest, which lasted for a considerable time, and which was not very honourable to either party. Wolf having delivered a dissertation on his quitting the pro-rectorate of Halle university in 1721, on which he took occasion to compare his own principles with those of Confucius and the Chinese, and having announced the opinion which he entertained on the doctrine of necessity, an outcry was raised against him, and he was represented by his enemies as a man whose principles tended to atheism, and to corrupt the morals of the people. Notwithstanding

this malignant attack, he employed himself in publishing three volumes of experimental philosophy, and a volume of dogmatical philosophy, which he dedicated to the emperor of Russia, and which the emperor caused to be translated into the Russian language, repeating to him the offers which had before been made, in order to induce him to remove to Peterburgh. The contest that had been excited against him still continued; and though he attempted to justify himself in a treatise on the subject of fatality, the king was at length persuaded that his principles were dangerous, and ordered him, in November 1723, to quit his territories in two days, under pain of death. Wolf immediately proceeded to Cassel, where he met with the king of Sweden, who appointed him professor of mathematics at Marburg, an office which he had refused sixteen years before. The clergy of Halle pursued him with their enmity and opposition to Marburg; but Wolf was suffered to remain in the quiet enjoyment of his office during his residence at that place. Several students who attended him at Halle followed him hither, and his lectures, which he commenced in 1724, were attended by pupils from all parts of Europe. His mind being now undisturbed, he resumed his literary labours, and published his "Remarks on Metaphysics," in which he answered the principal objections against his doctrine, and gained a decided victory over his enemies. The grounds of the censure that had been passed on Wolf had been every where canvassed; and almost every German university was inflamed with disputes on the subject of liberty and necessity, so that the names of Wolfian and anti-Wolfian were every where heard. Wolf, having thus vindicated his philosophy from reproach, received new invitations from Petersburg and Leipzig; but gratitude to his protector induced him to remain in his situation at Marburg, which he found to be very agreeable, and to afford him leisure for pursuing his speculations. After an interval of nine years, the current of public opinion turned in favour of Wolf, and he now received numerous tokens of respect from men of rank and learning; and in 1733 he was invited to fill, in the Academy of Sciences, one of the eight places allotted to foreigners distinguished in the highest branches of science. On this occasion, Reaumur and he commenced an intimate friendship, which lasted till the time of his death. The king of Prussia was convinced of Wolf's innocence, reversed his sentence of exile, and wished to repair the injury which he had sustained. He made tempting offers, both of title and money, to induce him to return to Halle; but he declined the acceptance of them; as he also refused an invitation from George I. of England to accept a place in the new academy which he had founded at Gottingen. The clergy of Halle made some other attempts to reproach and ruin him, but they recoiled on his adversaries. In the year 1740, he prefixed to the first volume of his "Droit Naturel, or Treatise on the Law of Nature," a dedication to the hereditary prince of Prussia, afterwards Frederick the Great, which was acknowledged by a very flattering letter.

Frederick the Great, as soon as he ascended the throne, recalled Wolf to Halle; and with the permission of the king of Sweden, he consented to accept the office of professor of the law of nature and nations, and also of mathematics, with a salary of 2000 crowns, and liberty to teach whatever he thought proper. He obtained also the rank of privy-counsellor, and was made first vice-chancellor, and afterwards chancellor of the university. In 1745 he was created a baron by the elector of Bavaria. Wolf was now at the height of his prosperity. At more than 60 years of age he resumed his labours, and completed his work on the law of

nature and nations, which was written in Latin, and extended to eight volumes 4to. He also wrote prefaces to the works of others, and particularly one to *Suffmilch's* work on population. Notwithstanding his great celebrity, perhaps on this account, he had many and powerful enemies. Leibnitz, Maupertuis, and Voltaire, were of this number: and with respect to the latter, we may observe, that both in his writings and in his conversation with the king, he contributed in no small degree to lessen the veneration which Frederick II. entertained for him. In 1752 he was made a member of the Institute at Bologna; but he did not long survive this honour, as he died in the month of April 1754, in the 76th year of his age. He left one son, who inherited a considerable estate which he had purchased.

The adversaries of Wolf attacked not only the principles of his philosophy, but his method and his style. His Latin, it must be acknowledged, was not elegant; but his German has been commended and imitated; and he is said to have improved his native tongue both in precision and energy. With regard to his general disposition and demeanour, he is said to have united a great degree of complaisance and affability, with irreproachable morals and excessive vanity, which he was not able to conceal. He did not hesitate to extol himself and his own merits publicly and without reserve, and even to exhibit them in emblematical devices on the titles of his books. Brueker sums up the character of Wolf as a writer in the following concise manner:—"He possessed a clear and methodical understanding, which by long exercise in mathematical investigations was particularly fitted for the employment of digesting the several branches of knowledge into regular systems; and his fertile powers of invention enabled him to enrich almost every field of science in which he laboured, with some new addition. The lucid order which appears in all his writings enables his reader to follow his conceptions with ease and certainty through the longest train of reasoning. But the close connection of the several parts of his works, together with the vast variety and extent of the subjects on which he treats, renders it impracticable to give a summary of his doctrines." Brueker's *Philosophy* by Enfield, vol. ii. Preface to M. de Vattel's *Law of Nations*. See *LEIBNITZIAN Philosophy*.

WOLF, JEROME, a German philosopher, was born in the county of Oettingen, in the year 1516, and instructed in the elementary parts of education at a college established by the senate of Nuremberg. But his studies were interrupted by an appointment in the service of Julius, the chancellor of count Von Oettingen. This interruption, however, contributed to allay the severity of his countenance and manner, and to meliorate the moroseness of his temper; whilst these unamiable qualities were amply counterbalanced by probity, diligence, and modesty, which engaged the confidence and esteem of his employer. His habitual disposition again returned, and he resumed the study of poetry, and of the ancient Greek writers, against the remonstrances of the chancellor, who recommended attention to jurisprudence and public business, as the most effectual means of acquiring both honour and competence. Remonstrances were ineffectual, and he persisted in pursuing a course which cherished his morbid melancholy and disquieting irritability. Still devoted to his literary pursuits, he was fortunate in gaining the patronage of John James Fugger; and in being afterwards advanced to the post of the director of the college of Augsburg, and that of librarian to this institution. In this situation he remained till his death, which happened in the month of October 1580. Wolf was particularly distinguished as a laborious translator, in which literary depart-

ment he gained the commendation of Huet; though Henry Stephen censures his performances. When the edition of the *Annals of Zonaras*, published by Wolf at Basle in 1557, became rare, a new one, with notes by Du Cange, was printed at the Louvre in Paris in 1687. Wolf's translation of Demosthenes was first printed at Basle by Oporinus; and being much approved, it passed through two other editions. After being revised by the translator, Episcopius printed it at Basle in 1572, with the orations of Æschines, the commentaries of Ulpian, and the notes of Wolfius. His other works, which were numerous, almost wholly related to Greek and Latin authors. *Eloges par Formey et Teiffier*.

WOLF, JOHN CHRISTOPHER, a German Lutheran divine and eminent scholar, was born in 1613, at Wernigeroda, and removing in 1695 to Hamburg, was educated under the protection of the celebrated Fabricius, by whom he was employed, under the age of 20 years, in making a catalogue of all the writers quoted in Eusebius's Commentary on Homer, afterwards inserted by Fabricius in his "*Bibliotheca Græca*." Having prosecuted his studies at Wittenberg, and graduated master of arts, he became, in 1706, adjunct of the philosophical faculty. Upon his return to Hamburg, he undertook a tour in 1708 through Holland to England, and for some time resided at Oxford for the use of the Bodleian library. His next migration to Denmark led, in 1710, to the appointment of extraordinary professor of philosophy at Wittenberg, where his lectures collected a great number of pupils. Although he was here advanced to the chair of theology, he removed in 1712 to Hamburg, and was appointed professor of the oriental languages in the Gymnasium, and in 1715 promoted to be rector of that institution. He was likewise a preacher-extraordinary at the cathedral, and became pastor of the church of St. Catharine; and soon after a member of the Academy of Sciences at Berlin. He commenced his literary contributions to the "*Acta Eruditorum*" in 1708; and he collected from various repositories an astonishing number of rabbinical and oriental books and MSS.; which library he bequeathed to the library at Hamburg, where he died in June 1739. Of his numerous works, we shall here enumerate his "*Bibliotheca Hebræa*," in 4 vols. fol.; "*Historia Lexicorum Hebraicorum*;" "*Primitiæ Flemburgenses, sive Oratio de Præcocibus eruditis, et Orationes binæ de Necessitate et Utilitate declamandi*;" "*Historia Bomogilorum*;" "*Disertatio de Atheismi falso suspectis*;" "*Curæ philologicæ et criticæ in Novum Testamentum*," 4 vols. 4to. He was also the editor of several learned works. *Gen. Biog.*

WOLF. There are biographical articles for five German musicians of that name in Gerber's Continuation of *Walther's Musical Lexicon*.

First, *Michael Christian Wolf*, organist and music director in St. Mary's church at Stettin, born 1709, and who died in 1789, after publishing the following works: "Six Duets for two German Flutes at Berlin;" "Six Harpichord Sonatas," Stettin, 1776; "Songs with a Harpichord or Harp Accompaniment," Emden, 1777; "Exercises for the Organ in Choral Music;" and having in MS. a Psalm for Four Voices, with an Accompaniment for the Organ, and many other pieces for the church and chamber.

II. *Ernst Friederic Wolf*, brother to the preceding matter, state organist at Cologne, who died in 1772. He had been two years under the chapel-master Stölz, for composition; and under the concert-master Hübn, at Gotha, for the violin. But at nine years old he had previously studied the scores of great masters, and the *Gradus ad Parnassum*

of Fouché, so that early in life he became a great extempore player on the organ.

Of these two brothers we have never heard or seen the productions; but of

Ernst William Wolf, born at a village near Gotha, in 1735, chapel-master at Weimer, we have seen and admired many of the works.

WOLF, in *Astronomy*. See **LUPUS**.

WOLF, *Lupus*, in *Zoology*, the *canis lupus* of Linnæus, a beast of prey of the dog kind, with the tail bending inwards, rather long and bushy, and the largest and fiercest of that race of animals. It is extremely like the domestic dog in shape, and if the head, which is long, with a pointed nose, did not differ a little in figure, the upper part of the face being broader, one would be apt to declare it the very same animal. It is distinguished also by superior size, stronger limbs, and more muscular body. It has a very fierce look about the face; its eyes are more obliquely placed than those of the dog, and are more glaring and savage; its jaws are much stronger; and its teeth, which are large and sharp, and the opening of its mouth, which is shorter in proportion than that of the dog, fierce and frightful. The ancients had an opinion, that the neck of the wolf was all of one solid bone; but, on the contrary, this creature is able to turn and twist it about better than the dog kind.

The wolf, as well as all the other beasts of prey, can endure hunger a long time, though very voracious when it meets with food. The wolf differs from the dog in his note, for instead of the barking of the dog this creature only howls; his ears, which stand erect, and his tail, make him also greatly resemble the fox.

The hair of the wolf is long; the legs are long; the head and neck cinereous: and the body generally pale grey, tinged with yellow; sometimes found white; in Canada sometimes black; and taller than a large grey-hound.

The wolf inhabits the continents of Europe, Asia, Africa, and America.

How numerous these animals were formerly in Britain we may infer from the laws of king Edgar, who attempted to extirpate them by commuting the punishments for certain crimes into the acceptance of a number of wolves' tongues from each criminal; in Wales by converting the tax of gold and silver into an annual tribute of three hundred wolves' heads. In succeeding times their destruction was promoted by certain rewards; and some lands were held on condition of destroying the wolves which infested those parts of the kingdom.

In 1281, these animals infested several of the English counties; but after that period, our records make no mention of them. The last wolf known in Scotland was killed in 1680, and in Ireland one was killed in 1710.

The wolves of North America are the smallest; and it is said, that from those proceeded the dogs which were found there by the Europeans on their first arrival: when reclaimed, they are the dogs of the natives. In the less inhabited parts of the country, they gather in large droves, and hunt the deer and other animals like hounds with hideous howlings, and it is affirmed that they will attack even the buffalo. In the inhabited parts, they are become rare. In some parts of Europe their number has somewhat increased; *e. g.* in Sweden they were rare till about the year 1720. The Swedes destroy them by stuffing the carcase of a sheep or other animal with a species of lichen or tree-moss, (*lichen vulpinus*), which is considered as a certain poison to the wolf, and also, as the name imports, to the fox. This is said to be mixed with pounded glass, which is probably more destructive than the lichen. The wolves of Senegal

are the largest and fiercest; and they prey in company with the lion. Those of the Cape are grey striped black; others are black.

Wolves are cruel, but cowardly animals; they fly from man, except when impelled by hunger; in which case, they prowl by night in great droves through villages, and destroy any persons they meet; and having once got the taste of human blood, give it the preference. In hard weather wolves assemble in large troops, and join in dreadful howlings. They have a fine scent, and hunt by the nose: between them and the dogs a mutual enmity subsists. This animal has a very strong carnivorous appetite; and yet crafty, strong, and nimble as he is, and in every respect capable of seizing his prey, he often dies of hunger. Being driven into the forest, he finds only a few species of wild animals, who save themselves by flight, so that he perishes with want. Although he is naturally timid and dastardly, he braves danger, when pressed with famine, and attacks those animals that are under the protection of man, and carries away lambs, small dogs, and kids, returning often to the charge, until being wounded by his pursuers, he retires to his den in the day, but issues forth in the night to his ferocious and destructive ravages. When his hunger is extreme, he attacks women and children, and sometimes darts with savage violence upon men, till at length he falls a sacrifice to his own rage. We have occasional accounts of the terror which this animal has excited, and of the destruction which he has committed among women and children in France. To such a degree did his ravages excite terror in 1764, that prayers are said to have been offered for his destruction.

Wolves, in the northern parts of the world, sometimes get on the ice of the sea, in order to prey on young seals, which they seize when asleep; but sometimes the ice detached from the shore carries them to a great distance from the land, and large districts have thus been cleared of these pernicious animals, which have been heard howling in a dreadful manner far in the sea.

The wolf is sometimes affected with madness, accompanied with symptoms similar to that of dogs; and this disease happens to them in the depth of winter, and therefore, as Mr. Pennant observes, cannot be attributed to the rage of the dog-days. The time of gestation in the wolf is, according to Buffon, about three months and a half; and the young whelps are found from the end of April to the beginning of July; and this difference in the time of gestation, being in the wolf about one hundred days, and in the dog only sixty, he considers as a proof of the real difference between the two species.

Although the wolf seems to be naturally savage, he is capable, when taken young, of being tamed, and of being wholly divested of the ferocious character of his species. Ray. Pennant. Shaw.

WOLF, *Golden*. See **JACKALL** and **AUREUS**.

WOLF, *Marine*. See **HYÆNA**.

WOLF, *Mexican*, *Canis Mexicanus*, with deflected tail and ash-coloured body, variegated with dusky bands and fulvous spots, a species that inhabits the hot parts of Mexico, agreeing in its manners with the European wolf. Its head, jaws, and teeth, are large; in the upper lips are strong bristles bent backwards, of a grey and white colour; the ears are large, erect, and cinereous, and the space between them marked with broad tawny spots; the head ash-coloured, crossed with dusky stripes; the neck fat and thick, and marked with a tawny stroke; on the breast is another of the same kind; the body is ash-coloured spotted with black, and the sides striped with the same colour; the belly

belly cinereous, the tail long, of the same colour, tinged in the middle with tawny; the legs and feet striped with black and ash-colour. This wolf is sometimes found white. Pennant.

WOLF, Black, *Canis Lycaon*, with straight tail, is considered by Buffon and others as a variety of the common wolf, and confounded by Schreber and Gmelin with the black fox; but regarded as a distinct species. It is found both in Europe and America, and in some parts of Asia. In America it is chiefly found in Canada, and in Europe in the more northern regions. Shaw.

WOLF, in the *History of Insects*, the name of a small white worm or maggot, which infests granaries, and does very great damage there.

It is in this state of the worm that it does the mischief; but this is not its perfect form, for it is afterwards transformed into a small moth, with white wings spotted with black.

This little maggot has six legs, and as it creeps along, there issues from its mouth an extremely fine thread or web, by which it fastens itself to every thing it touches, so that it cannot fall. Its mouth is furnished with a pair of reddish forceps, or biting instruments, by means of which it gnaws its way not only into wheat and other grain, but perforates even beams of wood, boxes, books, and every thing it meets with.

Towards the end of summer these pernicious insects may be seen crawling up the walls of corn-chambers, infested with them in great numbers; they are then searching a proper place where they may abide in safety during their aurelia state; for when the time of their undergoing this change approaches, they forsake their food, and the little cells they had formed of hollowed grains of corn clotted together, by means of the web coming from their mouths. They now wander about till they find some wood, or other substance into which they gnaw holes with their fangs, capable of concealing them; and there enveloping themselves in a covering of their own spinning, they soon become a dark-coloured sort of aurelia. They remain in this state all the winter; but in April or May they come forth in their moth-shape, and are then seen in vast numbers, taking short flights, and creeping up the walls. In this state they eat nothing; but they soon copulate and lay eggs, which are in the shape of a hen's egg, but no larger than a grain of sand. Each female lays sixty or seventy eggs, which she deposits in the little wrinkles of the grains of corn, where in about sixteen days they hatch, and the minute maggots immediately perforate the grain, and eat out all its substance, and with the threads which come from their mouths cement other grains to it, which they, in the same manner, scoop out and destroy.

The watchful observer has two opportunities of destroying these devourers from among his corn. One is, when they forsake their food, and ascend the walls, which they will sometimes almost cover. The other, when they appear in the moth-state. At both these times they may be crushed to death against the walls in great numbers, by clapping sacks upon them; but they may be exterminated more effectually by closing up all the windows and doors, and burning brimstone on a pan of charcoal, letting the room be full of the fumes of it for twenty-four hours. This certainly destroys the animals, and does no sort of injury to the grain, not communicating the slightest scent to it. Baker's Microf. p. 222.

WOLF's Bane, in *Botany*. See **ACONITUM**.

WOLF's Bane, Winter's, a species of *hellebore*; which see.

WOLF-Fish. See **LUPUS Marinus**.

WOLF's Grapes. See **LYCOSTAPHYLÆ**.

WOLF-Net, a term used by the sportsmen for a kind of net used in fishing, which takes great numbers, and has its name from the destruction it causes.

It is used both in rivers and ponds, and is of the nature of the rattle, excepting only the wanting of the four wings. The trunk or coffer consists of seven feet, besides the two gullets. It is supported by hoops, and is to be placed in some part where there is an abundance of sedges, rushes, and water-grafs. There is to be a place made for the net here, by the use of a paring-knife, cutting away all the weeds and other matter, for the space that will contain it; and when the net is placed, there are to be two alleys cut or cleared in the same manner, one on each side of the net, that the fish may be invited into them, and by them into the net. There must be some stones or leaden weights used to sink the net, and a long pole fastened to the upper part of the mouth of it, by means of which, when it is well filled with fish, it may be lifted up and taken to the shore.

WOLF's Peach. See **LYCOPERSICON**.

WOLF, War, an ancient military machine, differently described by different writers. Procopius makes it a kind of portcullis, or rather a harrow for defending a gate. Matthew of Westminster, and Camden, describe it as a machine for throwing stones. "At the gates," says Procopius, (Hist. of the Gothic Wars, book i.) "they set up wolves in the following manner:—They erected two beams from the ground reaching to the battlements, and laid chequerwise pieces of wrought timber, some upright and some cros; they jointed them so that the mortising holes met one another; and before each joint stuck out a pointed piece of wood, like a thick spar, and fastening the cros timbers to another beam, which from the top reached half-way down: they laid the beams flat along upon the gates, and when an enemy approached, men above laid hold of the higher ends of the beams, and thrust them down, which falling suddenly among the assailants, with the wooden points sticking out, killed all upon whom they descended." Probably there was a chain or cord to draw back the machine after it had produced its effect.

The war-wolf, for throwing stones, is described by Matthew of Westminster, ann. 1304; by Camden, in his Remains, to which we refer; and also to Grose's Mil. Antiq. vol. i. p. 383.

WOLF Island, in *Geography*, an island in the North Atlantic ocean, near the east coast of Labrador. N. lat. 53° 55'. W. long. 55° 40'.—Also, an island at the north-east end of lake Ontario. N. lat. 44°. W. long. 76° 50'.—Also, an island in the gulf of St. Lawrence, near the fourth coast of Labrador. N. lat. 50° 2'. W. long. 60° 55'.—Also, a small island in the Atlantic, near the coast of Georgia. N. lat. 31° 19'. W. long. 81° 30'.

WOLF River, or *Chickaw Bluff*, a river of Georgia, which runs into the Mississippi, N. lat. 34° 45'. W. long. 90° 42'.

WOLF Rock, a very low, flat, rocky islet, in the North Pacific ocean, surrounded by rocks and breakers, which extend some distance from it; 10 miles from the southern coast of the Prince of Wales's Archipelago. N. lat. 55° 1'. E. long. 226° 42'.—Also, a rock near the east coast of Labrador, and not far from the island called Wolf island.—Also, a rock at the entrance of the English channel; 10 miles S. of Land's-End. N. lat. 49° 58'. W. long. 5° 45'.

WOLFBOROUGH, a township of New Hampshire,

shire, in the county of Strafford, on the Winnipicogee lake, containing 1376 inhabitants; 35 miles N.N.W. of Durham.

WOLFDORF, a town of Bohemia, in the circle of Leitmeritz; 7 miles N. of Kamnitz.

WOLFENBUTTEL, a principality which lately constituted a part of the duchy of Brunswick, divided into two parts by the principality of Halberstadt, and the diocese of Hildesheim. The north part is surrounded on the north by the principality of Lüneburg and the marquise of Brandenburg, on the east by the duchy of Magdeburg, on the south by the principality of Halberstadt, and on the west by the diocese of Hildesheim. The south part is bounded on the north by the bishopric of Hildesheim and the principality of Calenberg, on the east by the diocese of Hildesheim and the Harz forest, on the south by the principality of Grubenhagen and Calenberg, and on the west by the territories of the abbey of Corvey and Calenberg. The eastern half contains under it a part of the Harz forest, the mines and salt-works which the prince held in common with the elector of Brunswick Lüneburg. In the western half of this southern part is a part of the forest of Sollinger, consisting of oak and beech, with a chain of mountains covered with woods. Thus the southern part of the principality consists chiefly of hills and woods, with little arable land; but, on the other hand, has a great plenty of timber, iron, and glass-houses, the manufactures of which are greatly admired, particularly those of looking-glasses, with a fine porcelain manufacture, and the very rich mines and salt-works in the Harz forest. The north part of the principality is more level, and produces abundance of grain, flax, and hemp, together with various kinds of pulse and fruit. Their graziery here turns to very good account, besides which it has a salt-work. The culture of silk is now followed, and premiums are assigned by the prince for the encouragement of it. The Weser, the Leine, the Inner See, and the Ocker, are the principal rivers. In this principality are 18 towns, 386 villages, and 17 sees and convents. The established religion here is Lutheranism. The country of Brunswick was anciently under lords of its own, who possessed it as their absolute and hereditary property, and derived their lineage from Ludolphus, duke of Saxony; and, consequently, by his grandmother Hafala, or Gifela, from duke Witikind, whose daughter she was. From king Henry I., grandson to Ludolphus, was descended his son Henry, duke of Bavaria, among whose issue was count Bruno, on whom the emperor Otho conferred a tract of land in Saxony, near Brunswick, namely, Melverode and Hohenwart. Count Bruno, his son, enlarged Brunswick; and his son, count Ludolphus, on the demise of the emperor Henry II., was the first that obtained the full sovereignty over Brunswick and Tanwarderode, and died in 1038. His son Egbert I. became margrave of Thuringia and Misnia; and his son Egbert II. likewise attained to those dignities. This last prince being killed in battle, in 1091, his sister Gertrude succeeded to the country of Brunswick, which country she brought to her second husband, Henry the Fat, count of Nordheim; and by their daughter Ricienza it came to her husband Lothario, count of Supplinburg, afterwards emperor. By his daughter Gertrude it descended to her husband, Henry the Magnanimous, duke of Bavaria and Saxony, and thus to the house of Welpho. The principality of Wolfenbittel was possessed of a vote among the princes, both in the college of the princes of the empire, and likewise in the diet of Lower Saxony; in each of which, by virtue of an agreement concluded in 1706, when the seniority lies in the house of

Brunswick Wolfenbittel, it precedes those of the elector of Brunswick and Lüneburg, for Zelle, Grubenhagen, and Calenberg, but otherwise comes after them; farther, the house of Wolfenbittel, when senior, obtained the joint direction of the circle of Lower Saxony. In 1807, this principality was annexed to Westphalia.

WOLFENBUTTEL, a city of Westphalia, and capital of a principality of the same name, situated in a low marshy soil, on the Ocker; it is well built and fortified. In it is a chateau, a long time the residence of the dukes, in which is a noble library containing 120,000 volumes of printed books and manuscripts. The principal church contains the sepulchral monument of the dukes. Wolfenbittel very probably owes its name to the first builder of the palace, called Wolf, or Wolfer, or Wolfhard; 24 miles E. of Hildesheim. N. lat. 52° 10'. E. long. 10° 40'.

WOLFERSDORF, a town of Saxony, in the circle of Neustadt; 4 miles S.W. of Weyda.—Also, a town of Saxony, in the circle of Neustadt; 6 miles E.N.E. of Weyda.

WOLFERSDYCK, a small island of Zealand, between North and South Beveland.

WOLFERSHEIM, a town of Germany, in the principality of Solms Braunfels; 12 miles S.S.E. of Wetzlar.

WOLFERSTORFF, a town of Austria; 2 miles S.E. of Laab.

WOLFERZHAUSEN, a town of Bavaria; 12 miles N.E. of Weilheim.

WOLFESHEAD, or **WULVERSHEAD**, Saxon, *wulfer-head*, compounded of *wulf*, *wolf*, and *head*, *head*, *caput lupinum*, denoted the condition of those outlawed for criminal matters in the Saxon time, and not yielding themselves to justice. For if they could have been taken alive, they must have been brought to the king; and if they, for fear of being apprehended, did defend themselves, they might be slain, and their heads brought to the king; for their head was no more to be accounted of than a wolf's head. LL. Edw. in Lamb. fol. 127. and Braet. lib. iii. tract. 2. c. 11. See *CAPUT Lupinum*, and *OUTLAWRY*.

WOLFESTAAL, in *Geography*, a town of Austria; 2 miles E. of Hainburg.

WOLFFBACH, a town of Germany, in the lordship of Furstberg; 4 miles S.S.E. of Hazlach. N. lat. 48° 13'. E. long. 8° 16'.

WOLFFEG, a town of Austria; 5 miles N.W. of Schwanaftadt.

WOLFFEGG, or **WOLFECK**, a chateau and village of Germany, which gives the title of count to a noble family, divided into several branches, *viz.* Wolffegg Zeil, Wolffegg Zeil Wurzach, Wolffegg Wolffegg, and Wolffegg Waldsee; 10 miles W. of Leutkirch.

WOLFFEN, a town of Saxony; 3 miles N.W. of Bitterfeld.

WOLFFPASSING, a town of Austria; 9 miles S. of Ips.

WOLFFSHAGEN, a town of Brandenburg, in the Mark of Pregnitz; 6 miles W. of Pritzwalk.

WOLFGANG, a town of Germany, in the county of Henneberg, on an island in a lake; 7 miles S.W. of Meinungen.

WOLFGANG, *St.* a town of Austria; 3 miles S.S.W. of Aigen.—Also, a town of Austria; 1 mile N. of Kirschschlag.—Also, a town of Austria, on a lake, called the Abernsea, and St. Wolfgang's lake; 54 miles S.S.W. of Lintz.

Lintz. — Also, a town of Switzerland, in the canton of Zug; 4 miles W. of Zug.

WOLFGAST, or WOLGAST, a town of Anterior Pomerania, on the Pena, about three miles from the Baltic, with about 3500 inhabitants. It was anciently a considerable fortress, and residence of the dukes; 30 miles S.E. of Stralsund. N. lat. $54^{\circ} 2'$. E. long. $13^{\circ} 45'$.

WOLFIA, in *Botany*, a genus of Schreber's, seems by its orthography intended to commemorate Dr. de Wolf, of Dantzic, of whose whimsical attempt in the NOMENCLATURE of plants, we have given a sufficient account at the conclusion of that article. This writer, to whom the praise of labour and originality cannot be denied, and whose index, entitled *Concordantia Botanica*, is truly valuable, died in 1784, aged 60. There have been several German naturalists and physicians of the name of Wolf, but none eminent in botanical studies.—Schreb. Gen. 801.—Class and order, *Oständria Monogynia*. Nat. Ord. *Tribilatae*, Linn. *Sapindi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coloured: tube very short, somewhat dilated at the base, permanent: limb in five deep, linear, obtuse, moderately spreading segments. *Cor.* none. Nectary of eight linear, obtuse, villous, upright scales, one-third the length of the calyx, and inserted into it at the base of the limb. *Stam.* Filaments eight, awl-shaped, erect, the length of the calyx, into which they are inserted alternately with the scales of the nectary, in the same row; anthers ovate, attached by the back, erect, directed inwards. *Pist.* Germen superior, oblong, ending in a cylindrical upright style, the height of the stamens; stigma oblong, downy, unilateral. *Peric.* Berry? ovate, of one cell, somewhat six-sided, with three keels surrounding its summit. *Seeds* three, nearly ovate, oblique, externally gibbous, contracted below the middle, abrupt at the base, enclosed in a tunic.

Obf. There appear to be several feeds, some of which prove abortive.

We have tried in vain to guess any thing more respecting this genus than its natural order, of which there can be scarcely a doubt. No author has adopted *Wolfia*. There are, in its characters, some indications of *Jambolifera*, Willd. Sp. Pl. v. 2. 326. *Cyminosma*, Gærtn. t. 58, (which ought to have found a place in our 18th volume; see CALYPTANTHES also); and a botanist who compares Schreber's description, literally translated above, with *Jambolifera pedunculata*, will find several coincidences, which, allowing for one or two easy misconceptions, might almost persuade us he had described that plant; but still there are insuperable difficulties. Schreber's index directs us, at the word *Pitumba*, to the same number as his *Wolfia*, 1749. But no such synonym occurs there, nor, as far as we can find, elsewhere in his book. *Pee tumba*, Rheede Hort. Mal. v. 9. t. 46, is a *Justicia*, and can have no connection with the present plant. See other obscure genera, thus circumstanced, at the articles MEYERA, WHELERA, SPARTINA, and XYSTRIS.

WOLF-MONETH, a name given by our Saxon ancestors to the month of January, on account of the ravages committed by the wolves in that month through the severity of the cold.

WOLFRAM, in *Mineralogy*, an ore of tungsten. (See TUNGSTEN.) The colour of Wolfram is generally a brownish or greyish-black; it gives a reddish-brown streak when cut with the point of a knife, to which it yields readily, a property characteristic of this mineral. It occurs

both massive and crystallized, and in concentric lamellar concretions. The form of the crystal is a flat rectangular prism; the lateral planes are generally streaked longitudinally. The structure is lamellar, with a very distinct cleavage in one direction, and an indistinct cleavage at right angles to the former. The lustre of the principal cleavage is splendid or shining, and is metallic; that of the indistinct cleavage is glistering. The cross fracture is coarse-grained and uneven. It is brittle and frangible. The specific gravity of Wolfram is from 7.1 to 7.3. Before the blow-pipe it decrepitates, and melts with difficulty into a black slag.

The constituent parts of Wolfram, as given by Vauquelin, are,

Tungsten acid	-	-	-	67
Oxyd of iron	-	-	-	18
Oxyd of manganese	-	-	-	6
Silex	-	-	-	1.50

Wolfram most frequently occurs in veins with tin-stone, but may be distinguished from it by its greater degree of softness, and the reddish streak which it yields to the knife. It is common in many of the mines of Cornwall, and in those of Saxony, and of Zinnweld and Schlackenwald, in Bohemia. This mineral has not hitherto been applied to any useful purpose in the arts. It was originally mistaken for antimony, which by the alchymists was called the wolf, because it appeared to destroy the baser metals in the process of refining gold.

WOLFRAMITZ, in *Geography*, a town of Moravia, in the circle of Znaym; 20 miles N.E. of Znaym.

WOLFRAMITZKIRCHEN, a town of Moravia, in the circle of Znaym; 7 miles N.W. of Znaym.

WOLFSBACH, a river of Silesia, which runs into the Bober, near Loewenberg.

WOLFSBERG, a town of the duchy of Carinthia, on the river Levant, with a citadel; 10 miles N.N.W. of Lavamunt.

WOLFSDORF, a town of Prussia, in the province of Ermeland; 18 miles W.S.W. of Heilsberg.—Also, a town of Saxony, in the circle of Neustadt; 5 miles S.W. of Weyda.

WOLFSHAGEN, a town of the principality of Hesse Cassel, on the Erpe; 15 miles W. of Cassel. N. lat. $51^{\circ} 18'$. E. long. $9^{\circ} 10'$.

WOLFSON, a small island in the gulf of Finland. N. lat. $59^{\circ} 22'$. E. long. $24^{\circ} 44'$.

WOLFSPACH, a town of Austria; 8 miles E. of Steyr.

WOLFSTEIN, a town of France, in the department of Mont Tonnerre; 43 miles W.N.W. of Manheim.

WOLHAUSEN IM MARKT, a town of Switzerland, in the canton of Lucerne; 7 miles W.S.W. of Lucerne.

WOLIN, or WOLYNIE, a town of Bohemia, in the circle of Prachatitz; 8 miles N.N.W. of Prachatitz. N. lat. $49^{\circ} 10'$. E. long. $13^{\circ} 45'$.

WOLIN, a town of Brandenburg, in the Middle Mark; 10 miles S.S.W. of Brandenburg.

WOLKART, a mountain of Carinthia; 8 miles N.E. of Millstatt.

WOLKENMARCK. See VOLKENMARK.

WOLKENSTEIN, a town of Saxony, in the circle of Erzgebirg, with a citadel, situated on a rock, near the Zschopa. About half a league from the town are some warm medicinal baths; 13 miles S.S.E. of Chemnitz. N. lat. $50^{\circ} 36'$. E. long. $12^{\circ} 59'$.—Also, a town of the county of Tyrol; 3 miles W. of Lientz.

WOLKOMYSK, a town of Lithuania, in the palatinate of Novogrodek; 40 miles W.S.W. of Novogrodek.

WOLLACOMB BAY, a bay of England, on the west coast of Devonshire, situated to the north of Barnstaple bay.

WOLLAPALLAM, a town of Hindoostan; 10 miles E. of Coimbatore.

WOLLASTON, WILLIAM, in *Biography*, an ethical writer, was born in 1659 at Cotton Clanford, in Staffordshire, and finished his education as a pensioner of Sidney college, Cambridge. In 1681 he commenced M.A. and entered into deacon's orders. His first settlement was as an assistant in the free school at Birmingham, to which a small lectureship was annexed; and about four years afterwards he was advanced from this laborious situation to the office of second master in the same school. In 1688 a relation died, whose decease put him in possession of a considerable landed estate, upon which he removed to London, and marrying a lady of considerable fortune, he resided in Charterhouse-square. Dismissing all thoughts of church preferment, he devoted himself to the retirement of private life and to a course of study, comprehending the learned languages, together with Hebrew and Arabic. The first publication which issued from the press was a poem on Ecclesiastes, which he would afterwards have suppressed, from a conviction that his talents were not adapted to poetry. In the progress of his life and literary pursuits, he was so much amused by composition, that he wrote many treatises on various subjects, both in Latin and English, which he committed to the flames. Of the well-known work which has perpetuated his name, and which is intitled "The Religion of Nature delineated," he printed a few copies to be distributed among his friends in 1722, but his declining health prevented his completing his original design. However, in 1723 he was prevailed upon to revise what he had printed for publication, and it accordingly appeared in 1724, in which year he died, at the age of 65, leaving a large family, and having lost his wife, to whom he was affectionately attached, about four years before. In his private character he is said to have exemplified the virtues which his work inculcated. The system which he developed, and which founded morality upon "truth," excited much attention, and his book, though not written in a popular manner, passed through seven editions to the year 1750. The last of these editions includes an appendix, consisting of a translation of the Latin notes by Dr. J. Clarke, dean of Salisbury, undertaken at the particular request of queen Caroline, who was a great admirer of the work. Dr. Warburton, in his strictures on Wollaston's theory in his *Divine Legation*, honours the author by ranking him as "one of our most celebrated writers," and compliments him with having "demonstrated with greater clearness than any before him the natural essential difference of things;" and though modern systems have in a considerable degree antiquated that of Mr. Wollaston, the author must always be regarded as a man of extensive learning and strong reasoning powers. *Biog. Brit.*

WOLLERSDORF, in *Geography*, a town of Germany, in the margravate of Anspach; 10 miles E. of Anspach.

WOLLERSTORFF, a town of Austria; 5 miles W.N.W. of Neutatt.

WOLLIN, a town of Brandenburg, in the Ucker Mark; 10 miles E.S.E. of Prenzlau.

WOLLIN, a town of Anterior Pomerania, on the east coast of the island so called, separated from the continent of Pomerania by the river Drenow, over which is a bridge, at which all travellers pay a toll. In this town are a seat and

prefecture. It stands on the site of the ancient city of Julin, which was formerly so famous for its commerce, though its origin is very obscure. The first mention of this city in history occurs immediately after the time of Charlemagne; and in the 11th century its prosperity was such, that Adam Von Bremen speaks of it as the largest city at that time in Europe. So early as the records of the 12th century, it is called Wolin. In the year 1127, it was set on fire by lightning, and being built of wood, was entirely consumed. The Pomeranian bishopric, which had been erected there but two years before, was translated upon that to Usedom, but on the rebuilding of the city, was restored to it. In the year 1170, being taken by Woldemar I. king of Denmark, and Jaromar I. prince of Rugen, it was sacked and burned; and after retrieving this calamity was, in the year 1175, again set on fire, and utterly destroyed, inasmuch that in the very same year the duke of Pomerania removed the bishopric to Cammin. It was indeed rebuilt again, but never recovered its former greatness; 25 miles N. of Old Stettin. N. lat. 53° 48'. E. long. 14° 35'.

WOLLIN, an island formed at the mouth of the Oder, between the Baltic and the Frische Haff; the form of an irregular triangle, about thirty miles in circumference. This island is frequently in danger of being overflowed, and the sea-winds hurt it considerably, by throwing up drifts of sand. It produces excellent cattle, with plenty of game and fish; and one part of it, called the Pritter, is remarkable for the great quantity of eels taken there. Besides the town of Wollin, it contains several villages.

WOLLO, a town of Africa, on the Ivory Coast.

WOLLY. See **WOOLLI**.

WOLMIRSTADT, a town of Westphalia, in the duchy of Magdeburg. In the year 1642, this town was set on fire by the Imperial troops; 10 miles N. of Magdeburg. N. lat. 52° 18'. E. long. 11° 45'.

WOLMSDORF, or **WONSDORF**, a town of Prussia, in the province of Smalend; 24 miles S.E. of Königsberg.

WOLNITZ, a town of Saxony, in the principality of Eisenach; 2 miles S. of Jena.

WOLNZACH, a town of Bavaria; 6 miles N.E. of Pfaffenhofen.

WOLPA, a town of Lithuania, in the palatinate of Novogrodek; 54 miles W. of Novogrodek.

WOLPAFFING, a town of Austria; 4 miles S.S.E. of Weikerdorf.

WOLSDORFF, a town of the duchy of Bremen; 5 miles S. of Carlstadt.

WOLSEY, or **WULCEY**, THOMAS, cardinal, in *Biography*, was the son of a butcher at Ipswich, Suffolk, and born there in 1471. He finished his education at Magdalen college, Oxford, and was graduated B.A. at the age of 15. He was afterwards fellow of his college, and having taken the degree of M.A. became master of the school dependent upon that college, where he had under his tuition three sons of the marquis of Dorset, by whom he was presented to the rectory of Lymington in Somersetshire, into which he was inducted in 1500. His advancement was rapid, first as domestic chaplain to the archbishop of Canterbury, and afterwards as chaplain to the household of Henry VII. His manners were insinuating, and he became the confidante of the king, who communicated to him his projected marriage with the daughter of the emperor Maximilian. Wolsey met the emperor at Bruges, and executed his commission so much to the king's satisfaction, that he nominated him to the deanery of Lincoln. After the death of Henry VII. he was recommended by Fox, bishop of Winchester, to Henry VIII., whose

favour

favour and confidence he conciliated by his blending amusement with business, inasmuch that he supplanted the ministers of the late king, and became himself uncontrolled minister. His preferments, civil and ecclesiastical, very speedily succeeded one another, and even profusely accumulated. He was introduced into the privy-council in 1510, made reporter of the star-chamber, registrar, and afterwards chancellor of the garter; and advanced to the sees of Tournay and Lincoln in 1513, to that of York in 1514, and to the dignity of cardinal in 1515. Thus promoted, his pride and love of pomp kept pace with his elevation of rank. In his train of servants, 800 in number, were many knights and gentlemen; and the sons of noblemen acted occasionally as his domestic menials. His equipage and furniture were of the most costly kind; but it is needless to multiply particulars. The most pardonable, not to say laudable, display of his magnificence was exhibited in his patronage of literary men and promotion of literature, both by the exercise of private bounty and the establishment of public institutions. The pope nominated him legate à latere, by which office he acquired legal pre-eminence over the archbishop of Canterbury; and in December 1515, he was elevated to the office of high-chancellor. By the equity of his decisions in the exercise of this office he gained great credit; but his conduct as legate à latere was so arbitrary and oppressive, as to produce complaints against him to the king. Charles V. and Frederic I. purchased his interest with Henry VIII. by pensions, and he was also retained in the same way by the pope. Charles flattered him with hopes of the papal crown, and settled upon him the revenues of two bishoprics in Spain. Still insatiable in the pursuit of ecclesiastical preferments, he obtained the administration of the see of Bath and Wells, and the temporalities of the abbey of St. Alban's, to which were afterwards added successively the rich bishoprics of Durham and Winchester. His revenues, thus amounting nearly to that of the crown, were expended partly in the ostentation of pomp, and partly in laudable munificence. He founded several lectures at Oxford for liberal and useful studies, and at length erected in that university the celebrated college of Christchurch. He also established a collegiate school in his native town of Ipswich. The palace which he built at Hampton Court he presented, in 1528, to the king, and he further ingratiated himself with Henry by an arbitrary loan for the supply of his wants; but by these measures he became more and more odious to the nation. But his fall was approaching; and the first step to it was the divorce of queen Catharine. This was followed by the marriage of Henry with Ann Boleyn, whose influence was employed in effecting his downfall. At length the king, not without hesitation and reluctance, employed the dukes of Norfolk and Suffolk, in 1529, to require him to surrender the great seal, and to quit York-place, a palace which he had built in London, and which afterwards became a royal residence under the name of Whitehall. His furniture and plate were seized for the king's use, and he was ordered to retire to Esher, a palace which belonged to him as bishop of Winchester. These measures overwhelmed the favourite, destitute of any inward resources of magnanimity; and when he received a slight token of the king's favour in this state of mental depression, he was transported with joy, dismounted on meeting the messenger, and fell upon his knees in the dirt to receive the expression of his master's kindness. Henry, however, was capricious and inconstant; a cloud overspread this gleam, and Wolsey was ordered to be indicted in the star-chamber, and abandoned by his sovereign to the rigour of parliament. An accusation, consisting of 44 articles, was

exhibited against him by the house of lords; and in the commons, he was so ably defended by Thomas Cromwell, who had been raised by the cardinal from a low condition to a high station, that his enemies were defeated. They thus changed their plan, and indicted him upon the statute of provisors, which prohibited his procuring bulls from Rome, and which he had violated by obtaining the legantine power; and this was made the ground of a sentence, putting him out of the king's protection, forfeiting all his lands and goods, and declaring him liable to imprisonment. When these measures had induced him to resign to the king York-place with all its furniture, he obtained a full pardon for all his past offences, and the restoration of the revenues of his archbishopric, with part of his goods. But fresh tokens of royal displeasure awaited him. The earl of Northumberland was ordered to arrest him for high treason, and to conduct him to London for trial. In his way from York to London, he was seized with a disorder which obliged him to stop at Leicester, where he was hospitably received in the abbey. His disorder in a few days terminated his life, in the 60th year of his age. Shortly before he expired he closed a conversation with the constable of the Tower, which related to the king, with this exclamation, "Had but I served God as diligently as I have served the king, he would not have given me over in my grey hairs!" Thus he sunk to the grave as a victim to tyranny, but to a tyranny which he had himself formed; exhibiting an instructive example to all future ministers of the insecure possession of power and wealth acquired by extortion and oppression, and of the folly of placing confidence in princes embracing arbitrary and despotic measures, and governed by caprice and personal ambition. Biog. Brit.

The magnificence of the cardinal's chapel-establishment, as described by Cavendish, his contemporary and domestic, seems far to have surpassed that of the Roman pontiff himself.

"First, he had there a deane, a great divine, and a man of excellent learning; a sub-dean, a repeatour of the quire, a gospeller and epittollor; of singing priests, ten, a master of the children. The seculars of the chapell, being singing-men, twelve; singing-children, ten, with one servant to waite upon them. In the vestry, a yeoman and two grooms; over and besides other retainers that came thither at principal feasts. And for the furniture of his chapell, it passeth my weak capacity to declare the number of the costly ornaments and rich jewels that were occupied in the same. For I have seen in procession about the hall forty-four rich copes, besides the rich candlesticks, and other necessary ornaments to the furniture of the same."

The earl of Northumberland, whose passion for Ann Boleyn is supposed to have occasioned his disgrace at court, seems to have been treated with great insolence and indignity by the cardinal, who, by an extraordinary extension of power, demanded his choral books for the use of his own chapel. Letters concerning this requisition are still preserved in the family, in which the earl says, "I do perceayff my lorde cardinall's pleasour ys to have such boks as was in the chapell of my lat lorde and ffayther (vos soll Jhu pardon.) To the accomplishment of which, at your desyer, I am conformable, notwithstandinge I trust to be able ons to set up a chapell off myne owne.—I shall with all sped send up the boks unto my lord's grace, as to say iiij Antiffonars (Antiphoners), such as I think wher not seen a gret wyll—v Gralls (Graduals)—an Ordcorly (Ordinal)—a Manuall—viij Proffessionars (Processionals)." Northumberland Household Book.

WOLSINGHAM, in *Geography*, an irregular town in

the county of Durham, England, is pleasantly situated in the vale of the Wear, on a point of land formed by the confluence of that river and the Wescrow. The church is situated at the north side of the town on rising ground, but possesses nothing worthy of remark. Near it are some remains of a considerable building, inclosed with a deep moat, supposed by some writers to have been part of a monastery, which was founded by Henry de Pudsey; but Hutchinon, in his History of Durham, refers them to the ancient manor-house of the bishop's, which is mentioned in Hatfield's Survey. The inhabitants of this parish, according to the returns of 1811, are 1983, the houses 399. The views down the Wear from the hill above Wolvingham include a very extensive and beautifully diversified country. Between this town and Stanhope, the commencement of the lead district is every where intimated by large parcels of lead lying near the sides of the road, and from the blue unwholesome vapours arising from the smelting mills in Bollihope. On Bollihope common, in 1749, was found a Roman altar with an inscription. This town is 6 miles S.E. by S. from Stanhope, and 259 N.N.W. from London. Here is a market held on Tuesday, and a fair on the 18th of May. The petty sessions are holden here. The parish, which is large, consists of Bradley, Hilton-park, Thornley, Wolvingham town quarter, East side quarter, Park quarter, and South side quarter.—Beauties of England, Durham, vol. iv.; by J. Britton and E. W. Brayley.

WOLTA, a town of Bohemia, in the circle of Konigin-gratz; 2 miles N. of Trautenau.

WOLTERN, a town of Germany, in the county of Verden; 30 miles E. of Rotenburg.

WOLTERS DORF, a town of Saxony; 2 miles S.W. of Zahna.

WOLTIN, a town of Hinder Pomerania; 12 miles S.W. of Stargard.

WOLTZTORFF, a town of Austria; 2 miles N.N.W. of Weikerstorf.

WOLVERENE. See GLUTTON.

WOLVERHAMPTON, formerly HAMPTON, in *Geography*, an important market-town in the hundred of N. Seifdon, and county of Stafford, England, is particularly noted for its extensive manufactures of locks, keys, and other articles of ironmongery. It is situated on a rising ground 16 miles S. from Stafford, 14 S.W. from Lichfield, 13 N.W. from Birmingham, and 130 in the same direction from London. Wolverhampton is of ancient date, for as early as 996 a monastery was founded there by Wulfruna, from whom the town received the first member of its name. The institution, consisting of a dean and secular canons, was about the year 1200 transferred by the dean, Peter of Blois, to the archbishop of Canterbury, to convert it into an abbey for Cistercian monks; but this design seems not to have been executed, for the seculars appear to have been not long after in possession of the establishment. The church, which was considered as one of the king's free chapels, was by Edward IV. annexed to the deanery of Windfor; but in the seventh year of Edward VI. a grant of the college of Wolverhampton and seven prebends was made to John, duke of Northumberland. Coming again to the crown by his attainer, queen Mary reinstated the dean and prebendaries, and endowed them with all the lands, &c. which formerly belonged to the institution, then valued at the yearly rent of 113*l.* 13*s.* On a question arising concerning those possessions, the grants of Mary were confirmed by James I., who appointed the celebrated Marc-Antonio de Dominis, who had been archbishop of Spalatro in Dalmatia, to be dean of Windfor, and dean and first prebendary of Wolverhampton:

those deaneries continue to be united, but the colleges are separate.

Wolverhampton is well built, and considered as salubrious, notwithstanding it is in the vicinity of many coal-mines. The parish is of great extent, being nearly 30 miles in circuit, and comprehends, besides the town, seventeen considerable townships, or villages, among which are, Bilston, Featherstone, Hatherton, Hilton, and Kinvafton. According to the returns to parliament in 1811, the houses in the whole parish were 2936, and the inhabitants 14,836. A market is held on Wednesday, and a fair on the 10th of July. The skill and ingenuity of the lock-smiths of the town and the environs, (for many of the farmers themselves are concerned in the business,) and the trade carried on in these and similar articles of iron manufacture, are unparalleled in England: the trade is particularly promoted by the Staffordshire and Worcestershire grand trunk, and the Birmingham canals, which unite about a mile to the N. of the town. The town is governed by two constables, and in it are held the petty sessions for the N. and S. divisions of Seifdon hundred.

The collegiate church of St. Peter stands on an elevation on the E. side of the town, and consists of a lofty nave, with side-aisles and a chancel. From the centre of the building, which is of stone, rises a tower. The nave is separated from the aisles by five pointed arches, supported by octagonal pillars. Against one of the S. pillars is erected a very curious stone pulpit. The font, which is octagonal, and covered with sculptured figures, &c. appears to be very ancient. In the great chancel is a full-length statue, in brass, of the celebrated admiral sir Richard Leveson, who had a command against the Spanish armada, under sir Francis Drake. In the church-yard stands a round column twenty feet high, profusely but rudely carved in divisions, and the whole surmounted by a plain capital. It is evidently ancient, and may have supported a cross, or the figure of the patron-saint. The situation of Wulfruna's monastery is unknown; but in the S.W. corner of the burying-ground is a large room supported by groins, the walls of which are three yards in thickness. Besides St. Peter's, Wolverhampton possesses another church, dedicated to St. John, which was erected by subscription, and consecrated in 1761. Dissenters of various denominations abound in the parish of Wolverhampton, and comprehend more than one half of the inhabitants: chapels for their accommodation are consequently numerous. A free-school was founded here by sir Stephen Jennings of Wolverhampton, who was lord-mayor of London in 1668; besides which, charity-schools are maintained for children of both sexes. Bilston, a large and populous village two miles S.E. from the town, is within the parish of Wolverhampton; but as to all parochial concerns it is a separate township. In 1811 Bilston contained 1862 houses, and the inhabitants amounted to 9646. Here is a parochial chapel, which is a neat modern structure: the living is a perpetual curacy within the exempt jurisdiction of the dean of Wolverhampton; but the nomination and presentation of the incumbent are vested in the inhabitants at large. Bilston contains likewise two dissenting meetings, and an excellent charity-school. The business of Bilston consists chiefly of japanned and enamelled goods. The vicinity abounds in coal, iron-stone, with numerous smelting-furnaces and forges, &c. in which the operations are performed by steam-engines. Bilston furnishes also a peculiar kind of sand of great use in casting metals. At Bradley, near Bilston, the subterraneous coal has been burning for several years past, and every attempt to extinguish it has hitherto proved fruitless, by which several

val acres of land have been rendered unproductive. The fire proceeds from a burning stratum of coal about four feet thick, and eight or ten yards deep, to which the air has free access; as the main bed of coal has been dug out from under it. In collecting the calcined substances for repairing the roads, sulphur and alum are frequently found. Tatenhill, a small village on a steep eminence two miles N. from Wolverhampton, was the scene of a severe battle between Edward the Elder and the Danes, in the beginning of the 10th century. In this place was founded, before the Norman Conquest, a college with a dean and five prebends, which subsisted till the general dissolution by Henry VIII. The present church, or chapel, is apparently a part of that establishment. At Wrottesley, a village in the parish of Wolverhampton, extensive ancient remains have been discovered, supposed, by Dr. Plott, in his History of Staffordshire, to be vestiges of the old Theotenhall of the Danes: but later antiquaries imagine these remains to belong to the Uriconium of Roman Britain. The parish of Wolverhampton, although varied with eminences, is in general level, and ornamented with a number of agreeable hamlets and country-seats.—History and Antiquities of Staffordshire, by the Rev. Stebbing Shaw, fol. Lond. 1798. Beauties of England and Wales, Staffordshire, 8vo. Lond. 1814.

WOLVES-TEETH, of a horse, are overgrown grinders, the points of which, being higher than the rest, prick the creature's tongue and gums in feeding, so as to hinder chewing of the meat.

They are seldom met with but in young horses; but if they be not daily worn by chewing, they will grow up even to pierce the roof of the mouth.

There are usually two of these wolves-teeth, which are small, and grow in the upper-jaw, next to the great grinding-teeth: these are so tender and painful, that the horse cannot chew his meat, but is forced to let a great part of it fall out of his mouth, or swallow it half chewed.

The remedy, in this case, is to tie up the horse's head to some part of the rafter, and open his mouth with a cord; then with an instrument like a carpenter's gauge, and a mallet, the teeth that are thus troublesome are to be knocked out, and the holes filled up with salt.

If the upper-jaw teeth hang over those of the under-jaw, and by that means cut the mouth, the same instrument is to be used, and the teeth are to be pared shorter by little and little. When they are sufficiently pared down, they must be filed smooth, and the mouth washed with vinegar and salt, and the whole complaint will be thus removed.

WOLZ. See **WELS**.

WOMAN, **FEMINA**, *Mulier*, the female of man.

A woman, in England, as soon as she is married, with all her moveables, is wholly in *potestate viri*, or at the will and disposal of her husband.

There are divers considerable things relating to women in the laws of England, which see under **WIFE**.

St. Augustine calls women the *devout sex*; at least, this is the common opinion; though others rather think, that in the prayer usually attributed to that father, and still rehearsed in the Romish church to the Holy Virgin, the words

“intercede pro devoto fœmineo sexu,” are to be understood of women devoted or consecrated to God in religious houses; which had been sufficiently expressed by the words, “ora pro populo, interveni pro clero.”

It is a popular tradition among the Mahometans, which obtains to this day, that women shall not enter paradise.

An anonymous author, about the close of the sixteenth century, published a little Latin dissertation, to prove that women are not men; that is, are not reasonable creatures: “Dissertatio perjucunda, qua anonymus probare nititur mulieres homines non esse.” He also endeavours to prove, what naturally follows from this principle, *viz.* that women shall not be saved, that there is no future life or happiness for them. His proofs are all taken from Scripture, or founded on Scripture. Though, after all, his aim is not so much to degrade women to the condition of brutes, as to ridicule the principle or method of many Protestants, who, in points of controversy, admit of no proofs or considerations but what are taken from Scripture alone. This appears from the conclusion of the work. “Probavi, opinor, invictissimis SS. literarum testimoniis, mulierem non esse hominem, nec eam salvari: quod si non effeci, ostendi tamen universo mundo, quomodo hujus temporis hæretici, et præsertim Anabaptistæ, sacram soleant explicare Scripturam, et quo utantur methodo ad stabilienda sua execranda dogmata.”

Yet Simon Gediccus, a Lutheran divine, wrote a serious confutation of this piece in 1595, wherein the women are restored to the expectation of heaven, on their good behaviour.

The ancient Marcionites allowed their women to baptize; as we are assured by St. Epiphanius, Hær. 42. cap. 4. the Montanists admitted women to the priesthood, and even the episcopate, Epiph. Hær. 49. cap. 2. The modern Quakers also permit their women to preach and prophecy, on an equal footing with the men.

It is a point much controverted, how far learning and study become the sex? Erasmus handles the question at large in one of his letters to Budæus. Lud. Vives, in his *Institutio Fœminæ Christianæ*, has a chapter expressly on the same subject. Madam Schurman, a German lady, has gone beyond them both, in a treatise on this problem, “Num fœminæ Christianæ conveniat studium literarum?”

Several of the women remarkable for learning have been also distinguished for their want of conduct. The reason, no doubt, lay in this; that their first studies lying in books of gallantry and intrigue, the imagination was early turned that way, and the memory filled with a sort of ideas, which a favourable disposition, and age, adopted too easily, and improved too fast. It is not that study in itself has any natural tendency to produce such effects; rather the contrary: the close abstracted researches of metaphysics, logics, mathematics, physics, criticism, &c. no doubt would be the surest means to secure and establish the virtue of continency in a woman.

For an account of women hired to weep at funerals by the Romans, see **PRÆFICÆ**.

Women were allowed to sing, in 1772, in the collegiate church of St. Gudula, at Brussels. It was in the performance of high mass on a Sunday, when a considerable number of voices and instruments were assembled in the choir; and we were glad to find among the former two or three women, who though they were not fine singers, yet their being employed, proved that female voices might have admission in the church, without giving offence or scandal to piety, or even bigotry. If the practice were to become general, of admitting women to sing the soprano part in the cathedrals,

it would, in Italy, be a service to mankind, and in the rest of Europe render church music infinitely more pleasing and perfect; in general, the want of treble voices, at least of such as have had sufficient time to be polished, and rendered steady, destroys the effects of the best compositions, in which, if the principal melody be feeble, nothing but the subordinate parts, meant only as attendants, and to enrich the harmony of the whole, can be heard.

WOMEN, *Appeals of*. See APPEAL.

WOMEN, *Jury of*. See JURY of MATRONS.

WOMEN, *Stealing, or Seduction of*, is punishable by the statute 4 & 5 Ph. & Mar. cap. 8. which enacts, that if any person above the age of fourteen unlawfully shall convey or take away any woman child unmarried, (which is held to extend to bastards as well as to legitimate children,) within the age of sixteen years, from the possession and against the will of the father, mother, guardians, or governors, he shall be imprisoned two years, or fined at the discretion of the justices: and if he deflowers such maid or woman child, or, without the consent of parents, contracts matrimony with her, he shall be imprisoned five years, or fined at the discretion of the justices, and she shall forfeit her lands to her next of kin, during the life of her said husband. But this latter part of the act is now rendered almost useless, by provisions of a very different kind, which make the marriage totally void, in the statute 26 Geo. II. cap. 33. See MARRIAGE. See also FORCIBLE *Abduction, RAPE, and RAVISHMENT.*

WOMB, MATRIX, or *Uterus*, in *Anatomy*, that part of the female of any kind, wherein the fœtus is conceived and nourished till the time of its delivery.

The ancient Greeks called the *matrix*, $\mu\alpha\tau\epsilon\kappa\eta$, from $\mu\alpha\tau\epsilon\kappa\eta$, *mother*: whence disorders of the womb are still frequently called *fits of the mother*. They also call it $\upsilon\tau\epsilon\rho\eta$, as being the lair of the entrails, by its situation. Sometimes they also call it $\phi\upsilon\upsilon\sigma\iota\varsigma$, or *natura*; and *vulva*, from *volvo*, to fold, or *envelope*, or from *valvæ*, doors. See UTERUS.

WOMB, *Dropsy of the*. See DROPSY.

WOMB, *Ulcers of the*. See ULCERS.

WOMB, in *Geography*, a town of Sweden, in the province of Skonen; 12 miles E. of Lund.

WOMBACH, a town of Germany, in the county of Rieneck; 3 miles S. of Lohr.

WOMBAT, in *Zoology*, an animal of which Mr. E. Home has given an anatomical description in the 2d part of the 98th volume of the Philosophical Transactions. It was brought from the islands in Bassa's straits, and lived with him in a domesticated state for two years. Whenever it had an opportunity, it burrowed in the ground, and covered itself in the earth with surprising quickness. It was quiet in the day, but in constant motion during the night; very sensible of cold; ate all kinds of vegetables; was particularly fond of new hay, which it ate stalk by stalk. It appeared attached to those to whom it was accustomed, and who were kind to it. It allowed children to pull and carry it about, and when it bit them it was not in anger or with violence. It appeared to have arrived at its full growth, weighed about twenty pounds, and was about two feet two inches long. Another animal called the 'Koala,' is a species of the wombat, partaking of its peculiarities. It inhabits the forests of New Holland, about fifty or sixty miles S.W. of Port Jackson, whither it was brought in August 1803, and is called by the natives the 'koala wombat.' It is commonly about two feet long and one high; in the girth about

a foot and a half: it is covered with fine soft fur, lead-coloured on the back and white on the belly: the ears are short, erect, and pointed; the eyes generally ruminating, sometimes fiery and menacing: it bears no small resemblance to the bear in the fore-part of its body: it has no tail; and its customary posture is sitting. The New Hollanders eat the flesh of this animal; and are very dextrous in the pursuit of it, climbing with wonderful rapidity the loftiest gum-trees in search of it. The koala feeds upon the tender shoots of these trees; and during the day rests on the tops of them, either feeding at ease, or sleeping. In the night it descends, prowls about in search of some particular roots, creeping rather than walking; and when incensed or hungry, it utters a long shrill yell, and assumes a fierce and menacing look. These animals are found in pairs, and the young is carried by the mother on its shoulders. It soon forms an attachment to the person who feeds it.

The external form of the wombat has been described by M. Geoffroy, in the 2d volume of the "Annales du Muséum National de France;" and several parts of its internal structure have been taken notice of by M. Cuvier, in his "Leçons d'Anatomie Comparée." The mechanism of the bones and muscles of the hind legs differs in many respects from that of all other animals, except the koala. This has been minutely examined and described by Mr. Brodie, at the desire of Mr. Home; and it appears that there is nothing similar to it in the hind legs of the mole, or other burrowing animals. The internal structure of the wombat resembles that of the beaver; but it is so different from that of the kangaroo, and all the other animals of the opossum tribe, that it forms a very extraordinary peculiarity. The male and female organs of generation have been described; the former by M. Cuvier, and the latter by Mr. Bell in New South Wales. The male and female organs of the wombat and koala are similar to those of the opossum; and hence it is concluded, that these animals form the intermediate link between the opossum and kangaroo. See DIDELPHIS.

WOMBINELLORE, in *Geography*, a town of Hindoostan, in Baramaul. It was taken by the British, under general Meadows; 100 miles S.E. of Seringapatam. N. lat. 11° 43'. E. long. 78° 15'.

WOMBORN, a township of England, in Staffordshire; 3 miles S.W. of Wolverhampton.

WOMELSDORF, a town of Pennsylvania; 15 miles W. of Reading.

WONDA, a town of Africa, in Manding; 30 miles N.E. of Kamalia. See MANDING.

WONDA, a river of Manding, which, at Fonilla, a small walled village on its banks, is called Ba Woolima (red river); and towards its source it has the name of Ba Qui (white river); the middle part of its course being called Wonda.

WONDER. See MIRACLE.

The seven wonders of the world, as they are popularly called, were, the Egyptian pyramids; the mausoleum erected by Artemisia; the temple of Diana at Ephesus; the walls and hanging gardens of the city of Babylon; the colossus, or brazen image of the sun, at Rhodes; the statue of Jupiter Olympius; and the pharos, or watch-tower, of Ptolemy Philadelphus: instead of the latter, some reckon the royal palace of Cyrus, built by Menon, the stones of which were cemented with gold. See PYRAMID.

WONDERFUL WATER. See WATER.

WONDRA, or WONDREE, in *Geography*, a river which rises in Bavaria, and runs into the Egra, near Königberg, in Bohemia.

WONDRZEGOW, a town of Bohemia, in the circle of Kaurzim; 10 miles W.S.W. of Kaurzim.

WONSDORF,

WONSDORF, a town of Prussia, in Natangen ; 25 miles S.E. of Königsberg.

WONSIEDEL. See WUNSIEDEL.

WONTAMITTA, a town of Hindoostan, in Mysore ; 45 miles E. of Chinna Balabarum.

WOO-CHIN, a town of China, in the province of Kiangsi, near the lake Poyang, which is a place of considerable importance, as the great mart for exchanging commodities between the north and south of China. The warehouses are spacious and well filled, dwelling-houses large and substantial, temples richly decorated, and the shops filled with articles of all kinds, including no inconsiderable proportion of European goods. Here are several small bronze vessels of ancient and modern workmanship, not unlike the Grecian and Etruscan. Near it is a temple dedicated to Wang-shinchoo, the god of longevity, surpassing most others in riches of carved-work and gilding.

WOOD, WILLIAM, F.L.S., in *Biography*, a Protestant dissenting minister of distinguished reputation for general literature and science, character, and usefulness, was born at Collingtree, a village near Northampton, on May 29, O.S. 1745. His father, though occupying a humble station, was a person of approved integrity and piety, in connection with the Christian society at Northampton, under the personal care of the justly-celebrated Dr. Doddridge, and paid particular attention to the religious instruction and moral conduct of his children. Mr. Wood, at an early age, manifested promising talents, and having finished his school-education under the late Dr. Addington of Market-Harborough, was introduced, at the age of 16, with a view to the ministry, among Protestant dissenters, which was the object of his choice, to a dissenting academy in London, conducted at the time of his admission by Dr. David Jennings and Mr. (afterwards Dr.) Morton Savage, and before the close of his studies by Mr. Savage, Mr. A. Kippis, and Mr. A. Rees. The writer of this sketch can bear personal testimony to his exemplary conduct during the period of his continuance at the academy, and to the diligence and success with which he prosecuted the various branches of literature and science to which his attention was directed. Few persons ever left a public seminary with superior qualifications for the exercise of the profession to which he was devoted, and performed the duties of it, in the progress of a long and honourable life, more acceptably and more usefully. It was then the custom, admitting of few exceptions, to ordain ministers when they were elected by particular congregations, and introduced into the full discharge of the pastoral office ; and some, we understand, of the wisest and best of the Non-conformist ministers have lamented the too general discontinuance of this decorous practice, against which it is thought by many that no sufficient objection has been alleged. Ordination among Protestant dissenters is a public service, usually conducted at the place where the minister, who is ordained or set apart, is about to be settled ; and consists of a sermon addressed to the people, a charge delivered to the person ordained, and prayers for a divine blessing on his future labours, and for the edification and prosperity of the Christian society with which he is connected. It has been sometimes accompanied with a confession of faith on the part of the person who is thus set apart ; but this part of the service, having been misunderstood, is frequently omitted, though in cases which allow of unrestricted liberty, and in which the confession neither descends into a variety of minute particulars, nor contains any pledges that embarrass or restrain future free inquiry, it is thought to be unexceptionable. Ordination, however, among the persons to whom we now refer, is not conceived to impart any new qualifications or powers

which the person ordained did not possess previously to this service, or to constitute him either a minister in general, or the pastor of any particular church. But to return from this digression : Mr. Wood was publicly ordained, and the occasion afforded an opportunity for many ministers of acknowledged reputation among dissenters to bear their united testimony to his talents and character. He commenced his public services at Debenham in Suffolk, on the 6th of July 1766, with a sermon peculiarly appropriate to the occasion, from Luke, ix. 26., and he spent the remaining part of this year, and a great part of the year 1767, in the vicinity of London, where he occasionally officiated to the satisfaction of those who attended, and gained the friendship of some of the most eminent of the dissenting ministers of that period. In September 1767, he settled at Stamford, in Lincolnshire ; and removed from thence to Ipswich in November 1770, where he remained till the close of the year 1772. In 1773, having nearly completed his 27th year, he was unanimously chosen to succeed Dr. Priestley at Mill-hill chapel, Leeds, and in that connection he continued till his death. About two years after his settlement with this congregation, he published a small volume consisting of twelve sermons on social life, which entitled the author, in the judgment of a contemporary critic, to the character of a useful and elegant preacher. In 1780 he formed a matrimonial connection with a daughter of Mr. George Oates, of Low-hall, near Leeds, which lasted twenty-six years, and contributed in a high degree to his domestic felicity. By this lady he had four children, of whom three survived their parents.

Ardently devoted to the studies that were more immediately or more remotely connected with his profession, and attached by affectionate gratitude as well as interest to the congregation in the service of which he was engaged, and which claimed his most assiduous and respectful attention, he commenced for the benefit of the young a course of lectures, in the year 1785. These were comprehensive and improving ; and though they were delivered once a fortnight, they lasted several years. Our limits will not allow us to avail ourselves of the detail, furnished by his excellent biographer, of the subjects which were discussed in this extensive course of useful instruction. It will be sufficient to observe, that they contributed no less to the information of those who attended them than to the reputation of the lecturer, as well as to the mutual respect and esteem which were thus cemented between Mr. Wood and his congregation. The public would probably have derived instruction from the perusal of them, if some circumstances had not occurred which rendered it necessary for Mr. Wood to devote a considerable part of his time and attention to subjects of a very different nature. Without abandoning the studies connected with his profession, he was led by the state of his health, and by some other considerations, to the pursuit of natural history, and particularly of English botany ; but whilst he was thus occupied, he rendered his investigations subservient to the great object of his life and ministry, the promotion of religion and virtue, as well as the personal satisfaction and future happiness of those with whom he was connected. His new pursuits were the means of introducing him to acquaintance and friendship with many eminent persons ; and more especially with Dr. (now Sir James) Smith, the justly celebrated president of the Linnæan Society. To Mr. Wood the good opinion and friendly regard of *one*, who commands the respect and esteem of all who know him, by mental accomplishments and moral qualities of the most excellent and engaging kind, must have afforded a satisfaction which, as we can testify from personal know-

ledge, he very highly appreciated. The good opinion of such a judge of merit, in the department of natural history, which now engaged his attention, must have encouraged his assiduity and perseverance. He was thus qualified for contributing several valuable articles to this Cyclopædia, in the reputation and success of which the editor is happy to say he felt and expressed a peculiar interest. His contributions comprehended the botanical articles that occur, with some few exceptions, from the beginning of the letter B to the end of C; and the editor, who most sincerely lamented his death as a pupil and a friend, as well as a coadjutor in this work, would have found it difficult to supply the loss, if the kindness and condescension of the Linnæus of our time, for so, it is hoped, we may be allowed to denominate him without offending his delicacy, had not relieved his anxiety, and amply compensated the injury which the botanical department of the Cyclopædia must have sustained.

Mr. Wood had attained, by his talents and cultivation of them, to so high a rank among his brethren in that part of the country where his lot was cast, that few public services occurred in which he was not expected to be active and conspicuous. Attached to liberty, civil and religious, from his youth, he had in his maturer years thoroughly acquainted himself with the genuine principles of the British constitution; and accordingly he took occasion on the centenary of the Revolution, in 1788, to express his conviction and feelings in two sermons, which were afterwards published. In the three following years he took an active part in the application of the dissenters to parliament for the repeal of the test and corporation acts. In 1794 he preached a funeral sermon, on occasion of the death of the Rev. W. Turner, of Wakefield; and in the following year he performed the same service in consequence of the decease of the Rev. Mr. Ralph, of Halifax: the sermons which he delivered in both cases were published. The short account of Leeds which was this year communicated to Dr. Aikin for his History of Manchester deserves to be noticed, as he took great pains in exactly ascertaining the number of its inhabitants. About this time he commenced a course of education, addressed to young females, with a view partly to his own emolument, but principally for the benefit of those who were disposed to avail themselves of his instruction; and indeed few persons could be found capable of conducting such a course with greater satisfaction and advantage to those who attended it. His lectures occupied three years, and comprehended history, geography, natural philosophy, grammar, the belles lettres, natural history, mental and moral philosophy, and the evidences of natural and revealed religion. His next publication was his sermon occasioned by the death of the Rev. Newcome Cappe, which contained a very appropriate and justly-merited eulogy of his late revered friend. It was dedicated to Mrs. Cappe, who claimed from her talents and character, as well as relation to the deceased, a tribute of respect; and annexed to it some brief memoirs of Mr. Cappe's life. In the year 1801, Mr. Wood published a liturgy, consisting of five forms, for the use of his congregation at Mill-hill chapel, and composed, for the most part, from the service of the established church, the Liverpool, Shrewsbury, and other liturgies before published by the dissenters, as well as from a similar service composed by the Rev. T. Simpson. Of this performance it will be sufficient to state, that it was executed with judgment and taste. On the restoration of peace in the year 1802, he published an animated discourse, which he delivered, in the course of his public services, on that occasion. About this time he exerted himself in establishing at York the academical institution, which had for some years subsisted at Manchester, and which was

likely to be discontinued in consequence of the resignation of the late Rev. G. Walker, the theological tutor.

Intending, as he advanced in life, and when he had finished the education of his daughter, to relinquish the anxiety and labour of tuition, he proposed to engage in some literary undertakings. Accordingly he was a contributor, in the department of natural history, to the Annual Review; but the work which occupied his chief attention, and which afforded him the greatest pleasure, was the Cyclopædia already mentioned.

As a preacher, the last of his publications was a sermon delivered at Birmingham, June 9, 1805, for the benefit of the Protestant dissenting charity-school, supported by the joint contributions of the two societies of the old and new meeting-houses. After his return from an excursion in the months of July and August 1806, he was attacked by a severe paroxysm of the gout, to which he had been long subject; and in a few days his disorder was so alarming, that his recovery was not expected. As an aggravation of his distress, the affectionate partner of his life was seized with a disorder, which terminated in her death. For some time his state was such, that it was prudent to conceal from him both the progress and termination of her disorder. The mournful event which he had apprehended was gradually disclosed to him; and he received the afflictive intelligence with a degree of composure and resignation, which evinced the efficacy of his religious principles, and the consolation derived in such circumstances from Christian hope. During a long illness, which interrupted his public labours, and which was attended with a considerable expence, the society with which he was connected had an opportunity of testifying, by substantial acts of kindness, the high sense they entertained of his meritorious services. Providence at length restored his health to such a degree, that he was able to resume his public labours; but they were of no long continuance. On Sunday the 27th of March 1808, he performed the usual services with an uncommon degree of animation. On the following day, however, having previously experienced symptoms of a flying gout, he was suddenly seized at dinner with a violent sickness, which continued for many hours. This was succeeded by an inflammation of the bowels, which soon terminated in a mortification. The consequence was a delirium; and on Friday, the 1st of April, he expired so quietly, that the friends who attended his bed were not apprized of the moment of his departure. Those who wish for further information concerning the natural talents and acquired endowments, the private character and public services of Mr. Wood, will be amply gratified by the perusal of the "Memoirs of his Life and Writings," and of the "Address and Sermon" delivered on occasion of his death, by his friend and neighbour the Rev. Charles Wellbeloved of York.

WOOD, ANTHONY, the *Oxford Antiquary*, was born at Oxford in 1632, and entered of Merton college in 1647. Having commenced M.A. and acquired a taste for studies pertaining to antiquity, he pursued with indefatigable diligence both at Oxford and in London researches, which furnished him with materials for his "History and Antiquities of the University of Oxford," a copy of which he sold to the university in 1669 for 100*l.* It was written in English, but afterwards translated into Latin, under the inspection of Dr. Fell; and the version was published from the Oxford press in 1674, under the title of "Historia et Antiquitates Universitatis Oxoniensis, duobus Voluminibus comprehensa," fol. The first part of this work includes the annals of the university, from its earliest period to the year 1648; and the second contains an account of all its particular foundations, endowments, officers, &c. The translation

is badly executed, and Wood, the original author, was destitute of those qualifications that would have rendered him a fit historian of a learned university. Another of Wood's works was his "Athenæ Oxonienses; or, an Account, in English, of almost all the Writers educated at Oxford, and many of those at the Sister University, from the year 1500." It was first published in 1691, 2 vols. fol., and soon after subjected him to a prosecution in the vice-chancellor's court for his account of lord Clarendon, and to various other attacks, occasioned by his partialities, and more especially by his strong bias in favour of popery. His style is vulgar, and his sentiments illiberal and unphilosophical; but his veracity entitles him to confidence. He died in 1695, and bequeathed his books and papers to the university of Oxford. A second edition of this work, corrected and enlarged from the author's MS., was published in 1721. Biog. Brit.

This curious and diligent antiquary, whose whole life was spent in the service of the dead, and whose labours, since his decease, have so much facilitated the inquiries, and gratified the curiosity of the living, tells us, in the Memoirs of his Life, written by himself, with monastic simplicity, that in 1651, "he began to exercise his natural and insatiable genie to musick. He exercised his hand on the violin, and having a good eare to take any tune at first hearing, he could quickly draw it out from the violin, but not with the same tuning of strings that others used. He wanted understanding, friends, and money, to pick him out a good master, otherwise he might have equalled in that instrument, and in finging, any person then in the university. He had some companions that were musical, but they wanted instruction as well as he."

The next year, being obliged to go into the country to try to get rid of an obstinate ague, by exercise and change of air, he tells, that "while he continued there he followed the plow on well-dayes, and sometimes plowed. He learned there to ring on the six bells, then newly put up: and having had from his most tender yeares an extraordinary ravishing delight in musick, he practised there, without the help of an instructor, to play on the violin. It was then that he tuned his strings in 4ths, and not in 5ths, according to the manner; and having a good eare, and being ready to sing any tune upon hearing it once or twice, he could play it also in a short time with the said way of tuning, which was never knowne before."

"After he had spent the summer in a lonish and retired condition, he returned to Oxon. And being advised by some persons, he entertained a master of musick to teach him the usual way of playing on the violin; that is, by having every string tuned five notes lower than the other going before. The master was Charles Griffith, one of the musitians belonging to the city of Oxon., whom he then thought to be a most excellent artist. But when Anthony Wood improved himself in that instrument, he found he was not so. He gave him 2s. 6d. entrance, and so quarterly. This person, after he had extreamly wondered how he could play so many tunes as he did by 4ths, without a director or guide, tuned his violin by 5ths, and gave him instructions how to proceed, leaving then a lesson with him to practice against his next coming."

In 1653, he found that "heraldry, musick, and painting, did so much crowd upon him, that he could not avoid them; and could never give a reason why he should delight in those studies, more than in others, so prevalent was nature, mixed with a generosity of mind, and a hatred of all that was servile, sneaking, or advantageous for lucre sake."

"Having by 1654 obtained a proficiency in musick, he

and his companions were not without silly frolicks, not now to be maintained."—What should these frolics be, but to disguise themselves in poor habits, and like country-fiddlers scrape for their livings. After strolling about to Farringdon fair, and other places, and gaining money, victuals, and drink for their trouble, in returning home they were overtaken by certain foldiers, who forced them to play in the open field, and then left them without giving them a penny. "Most of his companions would afterwards glory in this, but he was ashamed, and could never endure to hear of it."

By 1656, his record informs us, that "he had a genuine skill in musick, and frequented the weekly meetings of musitians in the house of William Ellis, organist of St. John's college, situated on that place whereon the theatre was built." Here he gives a list of the usual company that met and performed their parts on lutes and viols; among these eight were gentlemen. "The musick-masters were, William Ellis, bachelor of musick, and owner of the house, who always played his part either on the organ or virginal. Dr. John Wilson, the public professor, the best at the lute in all England: he sometimes played on the lute, but mostly presided (directed) the consort. — Curteys, a lutenist, lately ejected from some choir or cathedral church. Thomas Jackson, a base-violist. Edward Low, then organist of Christ church: he played only on the organ, so when he played on that instrument, Mr. Ellis would take up the counter-tenor viol, if any person were wanting to performe that part. Gervase Littleton *alias* Westcot, or Westcot *alias* Littleton, a violist. He was afterwards a singing-man of St. John's college. William Glexney, who had belonged to a choir before the war: he played well upon the base-viol, and sometimes sung his part. — Proctor, a young man, and a new comer. John Packer, one of the universitie musitians; but Mr. Low, a proud man, could not endure any common musitian to come to the meeting, much less to play among them. Of this kind I must rank John Haselwood, an apothecary, a starched formal clisterpipe, who usually played on the base-viol, and sometimes on the counter-tenor. He was very conceited of his skill (though he had but little of it), and therefore would be ever and anon ready to take up a viol before his betters; which being observed by all, they usually called him Handlewood. The rest were but beginners. Proctor died soon after this time. He had been bred up by Mr. John Jenkins, the mirror and wonder of his age for musick, was excellent for the lra-viol and division-viol, good at the treble-viol and violin, and all comprehended in a man of three or four-and-twenty yeares of age. He was much admired at the meetings, and exceedingly pitied by all the faculty for his loss."

At this time Anthony Wood tells us, that "what by musick, and rare books that he found in the public library, his life was a perfect *Elysium*."

"Anthony Wood was now advised to entertain one William James, a dancing-master, to instruct him on the violin, who by some was accounted excellent on that instrument, and the rather because, it was said, that he had obtained his knowledge in dancing and musick in France. He spent in all half a yeare with him, and gained some improvement; yet at length he found him not a compleat master of his facultie, as Griffith and Parker were not: and, to say the truth, there was no compleat master in Oxon. for that instrument, because it had not been hitherto used in consort among gentlemen, only by common musitians, who played but two parts. The gentlemen in private meetings, which Anthony Wood frequented, played three, four, and five parts with viols, as treble-viol, tenor, counter-tenor, and

base,

bass, with an organ, virginal, or harpsicon, joyned with them; and they esteemed a violia to be an instrument only belonging to a common fiddler, and could not endure that it should come among them, for feare of making their meetings to be vaine and fiddling. But before the restoration of king Charles II., and especially after, viols began to be out of fashion, and only violins used, as treble violin, tenor, and base violin; and the king, according to the French mode, would have twenty-four violins playing before him, while he was at meales, as being more airie and brisk than viols."

"In the latter end of the yeare 1657, Davis Mell, the most eminent violinist of London, and clock-maker, being in Oxon., Peter Pitt, William Bull, Kenelm Digby, and others of All Soules, as also Anthony Wood, did give a very handsome entertainment in the tavern called the 'Salutation.' The company did look on Mr. Mell to have a prodigious hand on the violin, and they thought that no person, as all in London did, could goe beyond him."

By connecting the scattered fragments of this zealous Dilettante's life, which concern music, we shall be able to form an idea of the state of the art, not only at Oxford, but in every other part of the kingdom where it was more secretly practised during the latter part of the Usurpation.

Under the year 1658, Anthony Wood tells us, that "he entertained two eminent musicians of London, named John Gamble and Thomas Pratt, after they had entertained him with most excellent musick at the meeting-house of William Ellis. Gamble had obtained a great name among the people of Oxon. for his book of 'Ayres and Dialoges to be sung to the Theorbo; or Base-viol.' The other for several compositions, which they played in their consorts."

He then gives an account of the arrival of Baltzar, a wonderful performer on the violin, from Lubec, arriving at Oxford, and destroying, by his great superiority of hand, all the little vanities, not only of the best fiddle-players of the university, but of others from London, who had long enjoyed the reputation of great performers. See BALTZAR.

Anthony Wood pursues his musical records, and tells us, that "all the time he could spare from his beloved studies of English history, antiquities, heraldry, and genealogies, he spent in the most delightful facultie of musick, instrumental or vocal; and if he had missed the weekly meetings in the house of William Ellis, he could not well enjoy himself all the week after. Of all or most of the company, when he frequented that meeting, the names are set downe under the year 1656. As for those that came in after, and were now performers, and with whom Anthony Wood frequently played, were these: Charles Perot, M.A. fellow of Oriell college, a well-bred gentleman, and a person of a sweet nature; Christopher Harrison, M.A. fellow of Queen's college, a maggot-headed person, and humourous; Kenelm Digby, fellow of All Soule's college, he was afterwards Dr. of L., he was a violinist, and the two former violists; William Bull, M.A. for the viol and violin; John Vincent, M.A. a violist; Sylvanus Taylor, fellow of All Soule's college, violist and songster, his elder brother, captain Silas Taylor, was a composer of musick, played and sung his parts; Henry Langley, M.A. a violist and songster; Samuel Woodford, M.A. a violist; Francis Parry, M.A. a violist and songster; Christopher Coward, and Henry Bridgman, both masters of arts; Nathan Crew, M.A. a violinist and violist, but alwaies played out of tune, as having no good eare, he was afterwards bishop of Durham; Matthew Hutton, M.A. an excellent violist; Thomas Ken of New college, afterwards bishop of Bath and Wells, he would be sometimes among them and sing his part; Chris-

topher Jefferyes, a junior student of Christ church, excellent at the organ and virginals, or harpsicon, having been trained up to those instruments by his father George Jefferyes, organist to king Charles I. at Oxon.; Richard Rhodes, another junior student of Christ church, a confident Westmonasterian, a violinist to hold between his knees."

"These did frequent the weekly meetings, and by the help of publick masters of musick, who were mixed with them, they were much improved. Narcissus Marsh would come sometimes among them, but seldom played, because he had a weekly meeting in his chamber, where masters of musick would come, and some of the company before-mentioned. When he became principal of St. Alban's hall, he translated the meeting thither, and there it continued, when that meeting at Mr. Ellis's house was given over, and so it continued till he went over to Ireland, where he became afterwards archbishop of Tuam.

"After his majesty's restoration, when the masters of musick were restored to their several places that they before had lost, or gotten other preferment, the weekly meetings at Mr. Ellis's house began to decay, because they were only held up by scholars who wanted directors and instructors. So that these meetings were not continued above two or three yeares, and I think they did not go beyond 1662."

Our Oxford annalist terminates his account of the musical transactions of that university, during the interregnum, by the following anecdote.

"In October 1659, James Quin, M.A. and one of the senior students of Christ church, a Middlesex man borne, but son of Walter Quin, of Dublin, died in a crazed condition. Anthony Wood had some acquaintance with him, and hath several times heard him sing with great admiration. His voice was a bass, and he had a great command of it. 'Twas very strong and exceeding trouling, but he wanted skill, and could scarce sing in comfort. He had been turned out of his student's place by the visitors; but being well acquainted with some great men of those times, that loved musick, they introduced him into the company of Oliver Cromwell, the protector, who loved a good voice and instrumental musick well. He heard him sing with very great delight, liquored him with sack, and in conclusion said, 'Mr. Quin, you have done very well, what shall I do for you?' To which Quin made answer with great compliments, of which he had command with a great grace, that 'your highness would be pleased to restore him to his student's place;' which he did accordingly, and so kept it to his dying day."

If this minute and indiscriminate antiquary and biographer is sometimes thought to want taste and selection sufficient to give his records due weight, it must be ascribed to the constant habit he was in of journalizing, collecting anecdotes, and making memorandums of every person, transaction, and circumstance, that arrived at his knowledge, in the uncouth and antiquated language of his early youth. For this dialect being inelegant and vulgar, even when he learned it, renders his writings frequently ridiculous, though they contain such information as can be nowhere else obtained. But the few opportunities he had of knowing the gradual changes in our colloquial dialect, by conversing with men of the world, or even the language of elegant books by his favourite course of reading, degrade him to a level with writers infinitely his inferiors both in use and entertainment. An excellent apology has been made for his imperfections by the editor of his life, written by himself, and published in 1772; which is so interesting, that he must be an incurious inquirer, indeed, who, having dipped into it, is not sufficiently fascinated by the original simplicity of the style and importance

WOOD.

of many of the anecdotes, to give it an entire perusal before he lays it down. Anthony Wood was credulous, and perhaps too much an enthusiast in music to speak of its effects with critical and philosophical precision; however, without his assistance, the state of the art at Oxford, and the academical honours bestowed on its professors, as well as memoirs of their lives and works, would have been difficult to find. Upon his decisions in matters of taste, we are not always perhaps implicitly to rely. The high character he has given Dr. Willon's productions and abilities may have proceeded from want of experience, knowledge, and penetration into the finer parts of the art; and as to Dr. Rogers, his judgment of him seems to have been manifestly warped by friendship. Yet, upon the whole, it must be allowed that it is only from such minute records as those of Anthony Wood that any true and satisfactory knowledge can be acquired of the characters, manners, and domestic occurrences of our ancestors. The great features of history, and the events which occasion the ruin or prosperity of a state, must be nearly the same in every age and country; but comforts, conveniences, and the distresses of private life, furnish the mind with reflections far more varied and interesting to the generality of mankind, than the rise of states or downfall of kings and heroes.

WOOD, —, a performer on the violin, who led the band many years at the theatre in Covent Garden, and father of — Wood, his successor in that orchestra, organist of St. Giles's, and of Chelsea college. They were both active professors; but though performers only of the second class, they constantly ranked themselves of the first. Burney.

WOOD, in *Vegetable Anatomy*, is that more or less hard and compact substance, which makes up the bulk of the trunk and branches of a tree or shrub, and is concealed from view by the bark. When cut transversely, the wood is found to consist of numerous concentric layers, very distinct in the fir, and the trees of cold or temperate countries in general; less so in those appropriated to a tropical climate. The external part of each circular layer being much the most hard and compact, often with somewhat of a horny appearance, distinguishes the limits of each. Scarcely any two layers of the same tree are precisely alike, in the proportion which this compact part bears to the rest; nor does any one layer exhibit a precise uniformity of diameter in its whole circle. On the contrary, each layer is broader on that side of a tree where the exposure has been most favourable to its growth, where, consequently, there have been more branches and leaves, so as to yield a greater deposit of woody matter. Hence the layers being all, for the most part, broadest on one side of a tree, their aggregate disproportion throws the common centre, or pith, very much out of the actual centre of the trunk. It having been remarked in felling trees, that the greatest breadth of the concentric circles is very often on their south side, a rule has been proposed for travellers to ascertain thereby the direction of the compass. But travellers must be strangely at a loss, if they could find no easier method of judging. Nor is the mode in question infallible. It would indeed shew on which side the growth of each particular tree had been most favourable, whether from its exposure, or the nature of the soil which its roots had met with; but this may not always be towards the south. We must stay to fell great part of a forest, to form a precise opinion; and the process would be, as it were,

“ ——— to tell what hour o' the day,
The clock did strike—by algebra.”

The number of these concentric layers, in any tree,
VOL. XXXVIII.

if it be found to the heart, very correctly demonstrates the number of years the trunk has been growing. This is a general opinion, and undoubtedly correct, provided the layers are well marked. The observer must be aware that each annual layer is composed of a great number of thinner and scarcely distinguishable ones, which occasionally assume a more conspicuous appearance than usual, in consequence of fluctuating seasons, or any accidental checks in the growth of a tree, as hard winters render the outside, or horny part, of each circle, more decided; while favourable summers make the circle itself altogether broader. But there is always a sufficient distinction between summer and winter, beyond the tropics, to establish the above rule. Ever-greens, for the most part, and trees of hot countries, exhibit slighter traces of these concentric layers; but they may be discerned in every mahogany table. Monocotyledonous plants have been said to be entirely without any such annular structure. But there is no reason why they should necessarily be so. Mr. Salisbury once demonstrated this structure to us in a *Dracæna*; and its absence in palms and ferns is to be attributed to a peculiar mode of depositing wood in these plants, rather than to their being monocotyledonous. What has been said already under the articles *CIRCULATION of Sap*, and *CORTEX*, will sufficiently explain this. As the inner surface of the bark deposits the matter of the wood, it must lie in concentric circles; and in proportion as this operation goes on more constantly and uniformly, these layers must be the more homogeneous and uninterrupted. Perennial roots of herbaceous plants often exhibit concentric circles, of annular formation, even in hot climates, as may be seen in Jalap. Each circle, no doubt, marks the increase which has taken place in each successive season; and while the herb is not growing, nothing is added to the root.

The theory of vegetation, as explained in the articles just cited, shews the reason of the spiral-coated vessels being found in the young wood only, and not in the bark. Those vessels, formerly supposed to contain air alone, are the real arteries of the plant, and convey its sap, or blood, through the wood, to be returned through the bark, where it deposits particular secretions. This theory also explains why the *alburnum*, as being the layer of unhardened wood for the present year, is tender, and even a mere jelly, at one period. But the bark is in the spring of the year, before the deposit of wood begins, most readily stripped from the tree; though it also readily, and without harm to the tree, comes off in winter, while vegetation is at a stand.

We scarcely need here detail the experiments of Du Hamel, to determine whether the wood forms the bark, or the reverse. Thin metallic plates introduced between these two parts, and carefully bound up, shewed, after a few seasons, when the branch thus treated was cut across, that the bark had deposited layers of wood on the outside of these foreign substances, with little or no prejudice to the growth of the plant. But Dr. Hope's experiment (see *CORTEX*) is still more strikingly decisive. The Linnæan hypothesis, that the pith added a layer every year to the wood internally, is thus entirely set aside. Indeed nothing but a preconceived theory, of the great importance of the pith, and its analogy to the medullary or nervous system of animals, (for the support of which opinion arguments are not wanting,) could have led to so erroneous a conclusion. It is sufficient to remark, what indeed could not escape the intelligent author of this hypothesis, that trees grow vigorously, though their heart

is become rotten by age, when the pith, with numerous adjoining layers of wood, have long since been obliterated.

A transverse section of the wood of a tree displays various vessels, and other parts, which microscopic authors take delight in exhibiting; but, without a scientific explanation, little is to be learned from their plates, however beautiful to the eye. Siliceous petrifications, of oak-wood especially, fine specimens of which are brought from Hungary, shew its vascular structure in the greatest perfection. In the sections to which we have just alluded, the pith, with its highly cellular texture, makes a conspicuous appearance in the centre. In the body of the wood, the sap-vessels are generally the largest and most numerous. These, when young and tender, easily display their spiral coats, if pulled asunder longitudinally; but are not found at all in the bark. Among them, in the resinous trees like the fir, or any that abound with secreted fluids, as the fig, much larger vessels are interspersed through the wood and bark, in which the peculiar secretions are lodged. But besides the determinate and continued concentric layers of wood above-described, numerous thin plates are interspersed, known to workmen, especially in oak-wood, by the name of the SILVER GRAIN. (See that article.) Mr. Knight, who is there quoted, further remarks, that if a board of English oak be cut for a floor, in such a direction, that the *laminae* of the silver grain lie parallel with the surface of the board, it is rarely or never seen, when properly laid, to deviate from its true horizontal position. But a board sawed, on the contrary, across the silver grain, "will, during many years, be incapable of bearing changes of temperature, and of moisture, without being warped; nor will the strength of numerous nails be sufficient entirely to prevent the inconvenience thence arising. That surface of a board of this kind which grew nearest the centre of the tree, will always shew a tendency to become convex, and the opposite one concave, if placed in a situation where both sides are equally exposed to heat and moisture." *Knight, Phil. Trans. for 1801, 345.* This writer adds, that the small clefts in the surface of an oak-tree, stripped of its bark, and exposed to the sun and air, are caused by the plates of the silver grain having parted from each other. They will long continue to open and close again with the changes of the weather. In the middle of a dry day they are open, but much less so during the night. After long exposure to the air and light, wood loses this property. *Knight* as above.

A different degree of hardness, and in some trees a remarkable difference of colour, exists between a number of the external concentric layers of the wood, and about as many or more of those next the centre. These latter are called the heart of the timber; the former the sap or *alburnum*; but these are vulgar appellations, and the latter especially are improper. The true *alburnum* is the layer of new unhardened wood of the present year, which also workmen often term the sap. The SAP, properly so called, is the fluid from which all their secretions, and even the wood itself, are formed. (See that article.) Those who use wood for mechanical purposes are well aware of the above difference between its different parts, however incorrect the names by which they are distinguished. The softer external layers have little durability in comparison with the heart. They retain more of the vital principle, and more of the peculiar juices of the plant in a fluctuating condition, liable to be acted upon by external or internal causes, and not yet united, in a fixed state, to the solid body of the old

wood. This change, however, is not limited in any particular kind of tree to a determinate period in the age of each layer of its wood, nor even to any determinate series of the concentric circles of any individual tree. It often extends to a greater number of rings on one side than on another. The more vigour there is in a tree, or in any side or portion of its trunk, the sooner is the *alburnum*, to use its popular denomination, made perfect wood, or heart.

The term wood, philosophically speaking, is not confined to the substance of a tree. The central part of a root, distinguished from its bark, is the wood, and in many perennial roots consists, as we have already mentioned, of several distinct layers. In a carrot, the yellow part is the wood, encompassed by a thick reddish bark. In a turnip, the woody part is of ample dimensions, while the bark is thin.

A most remarkable difference exists between the solidity of the wood in some trees and in others. Some wood is so heavy as to sink in water; some is as light as cork, or even lighter. In general, wood of different trees, of the same natural order, possesses similar properties and the same degree of value. But there is often, in the same genus, a most remarkable difference between the fitness of the wood of different species, for particular purposes. The oaks (see *QUERCUS*) abundantly exemplify this fact. The very hard and ponderous timber of *Q. Ilex*, the live oak, however lasting in a dry situation, is so prone to destruction when exposed to wet, as to be among the most worthless in the world; its hardness and heaviness only rendering it the less fit for use, where it would be likely to endure. On the other hand, many of this genus afford timber more or less useful in every circumstance and situation, among which our English *Q. Robur* stands pre-eminent. See *TIMBER*.

All kinds of wood are to be preserved from the worm, and from many other occasions of decay, by oily substances, particularly the essential oils of vegetables. Oil of spike is excellent, and oil of juniper, turpentine, or any other of this kind, will serve the purpose; these will preserve tables, instruments, &c. from being eaten to pieces by these vermin, and linseed-oil will serve in many cases to the same purpose; probably nut-oil will do also, and this is a sweeter oil, and a better varnish for wood.

The ingenious Dr. Hales, whose attention was uniformly directed to schemes of domestic or national benefit, was induced by the great damage done to shipping by worms to propose various methods for preventing it. Oily, unctuous materials, he apprehends, are not likely to penetrate deep into oak, which has a watery sap; but oil is known to penetrate far into fir, and to give it a very considerable degree of toughness. He therefore proposes to mix with oil applied to the fir-boards with which ships are sheathed some ingredient that is disagreeable to the worms; and he apprehends that a small proportion of verdigrise used in the operation of paying would be of great service: or if copperfilings were mixed with the paying, sea-water would turn them into verdigrise. It might be useful to soak planks in water strongly impregnated with verdigrise.

Mr. Reid recommends the trial of the acid juice of tar, prepared either with copperas or ochre, for preserving ships either from rotting or worms.

In the East Indies, it is said, they have an effectual way of preventing worms from destroying their ships, by paying them first with a mixture of mustard, oil, and lime of shells, and hog's blood: they then sheath the ship, and renew it after some years.

The following receipt has been recommended by a person who never knew it fail of success. Take 100 lbs. of the
fineit

finest pitch; melt it over a slow fire of coal, and add to it, when melted, 30 lbs. of rolled brimstone grossly bruised, and boil the whole till 30 lbs. are wasted. The matter thus prepared must be kept in casks in a dry place; and when it is to be used, melt 100 lbs. of it, and add gradually 35 lbs. of brick-dust or marble-dust, sifted and well heated. The composition, when used, must be very hot, and the boards dry.

An ingenious ship-builder observes, that turpentine and brimstone form the best composition he has met with, and comes home from a voyage with least damage.

East India ships are first sheathed, and that sheathing is filled with small broad-headed nails, which is a safe and effectual defence from the worms, and soon becomes a continued cake of rust, and not liable to be damaged by cables, or common accidents. See *PAY* and *SHIPS*.

The following, says Dr. Hales, is an approved method of preserving the boards and timber of out-door work: *viz.* melt 6 lbs. of pitch, and add, by sifting, 1 lb. of dried brown Spanish, or whiting, and a quart of linseed oil. Hales's *Ventilators*, part i. p. 164. part ii. p. 289, &c.

Dr. Lewis observes, that though tar has been used for preserving wood, and also for coating common tiles, in imitation of the black glazed tiles, which are sold at a much higher price, both tar and pitch are of themselves too soft for these intentions, being liable to be melted off by the summer heat: and, therefore, different powdery substances, as ashes, ochres, and other mineral pigments, have been mixed with them.

In the Swedish Transactions for 1740 and 1742, two compositions are recommended, which are said to be firm, durable, and glossy. One is prepared by melting the tar over a gentle fire, so as to make it fluid, but not to boil, and stirring in as much coal-dust or powdered charcoal as will render it thick: the other is prepared by mixing the melted tar with a sufficient quantity of lamp-black. Coatings formed of these mixtures are, however, liable to be considerably softened by the heat of the sun. The mixture of powdered pit-coal and melted tar, made of such a consistence as to be freely spread while warm with a brush, is less liable to soften than either of the other two. The tar obtained from coal, in the method lately discovered by the earl of Dundonald, appears from various testimonies of those who have tried it to be much better calculated to preserve wood and iron, as well on land as in water, than vegetable tar. It has also this peculiar advantage, that it will not admit or harbour those worms that are so injurious to the bottoms of ships at sea. See an *Account of the Qualities and Uses of Coal and Coal-varnish, &c.* by the Earl of Dundonald, 8vo. 1785.

Mr. Parkes recommends, for the preservation of wood, the tar which is obtained from the pyroligneous acid. See *TAR*.

Dr. Lewis observes, that the coating or painting of wood does not in all cases contribute to its preservation: unless the wood be very thoroughly dry, especially those kinds of wood whose juices are not oily or resinous, the painting, by confining the watery sap, hastens the corruption. *Com. Phil. Techn.* p. 363, &c. On this subject, see *TIMBER*.

Some of the West India trees afford a sort of timber which, if it would answer in point of size, would have great advantages over any of the European wood, in ship-building for the merchant-service, no worm ever touching this timber. The acajou, or tree which produces the cashew-nut, is of this kind; and there is a tree of Jamaica, known by the name of the *white-wood*, which has exactly the same

property, and so have many other of their trees. *Phil. Transf.* N^o 36.

To season wood expeditiously for sea-service, it has been usual to bake it in ovens.

The art of moulding wood is mentioned by Mr. Boyle as a desideratum in the art of carving. He says he had been credibly informed of its having been practised at the Hague; and suspects that it might have been performed by some menstruum that softens the wood, and afterwards allows it to harden again, in the manner that tortoise-shell is moulded. Or, perhaps, by reducing the wood into a powder, and then uniting it into a mass with strong but thin glue. And he adds, that having mixed saw-dust with a fine glue made of isinglass, slightly straining out what was superfluous through a piece of linen, the remainder, formed into a ball and dried, became so hard as to rebound when thrown against the floor. *Works abr.* vol. i. p. 130. See *GLUE*.

The people who work much in wood, and that about small works, find a very surprising difference in it, according to the different seasons at which the tree was cut down, and that not regularly the same in regard to all species, but different in regard to each. The button-mould makers find that the wood of the pear-tree, cut in summer, works toughest; holly, on the contrary, works toughest when cut in winter; box is mellowest when it has been cut in summer, but hardest when cut about Easter; hawthorn works mellow when cut about October, and the service is always tough if cut in summer. *Merret's Notes on Neri*, p. 263.

It is a very well-known quality of metals to be longer and larger when hot, and shorter and smaller when cold; a thousand experiments prove this, and the books of experimental philosophy have sufficiently expatiated upon it; on the contrary, it is found to be the property of wood, that it is longest in cold weather and shortest in hot; this change is owing to the remains of the sap yet in the wood, which being condensed by cold, is enlarged in its surface, as all liquors are, when frozen into ice; and shrinks into a less space or bulk again, when liquated by heat.

It follows from this that all wood must change its surface more or less, according as it contains more or less sap, and this may be made a test of great use for the determining what kinds of wood have most, and what least sap. This would be a very valuable piece of knowledge, since there are many uses for which that sort of wood must always serve best, which has the smallest quantity of sap remaining in it. See *HYGROSCOPE*.

Thus, in the great article of preserving flour, no barrels are at present used but those of seasoned dry oak; the whole advantage of this wood is, that it contains less sap than others; for the sap in the wood makes the flour damp, and it then becomes rancid, and breeds worms. (See *MEAL*.) So that if any other wood can by this means be found out to contain less sap, when dried in the common way, than oak does, it will be so much the better for this purpose; or, if a cheaper wood should be found only to contain as little sap as the oak, it would do as well, and the price of oak would be saved in these vessels.

A proper way of trying when the sap was sufficiently exhaled out of trees, might also be found by this experiment, and much benefit would accrue from it; for our ships, when made of timber not sufficiently dried, prove injurious to the health of people on board; and it has been remarked, both by the French and ourselves, that many more men in general die in the first voyage of a new ship than in the same time in an old one; and indeed the first six months are usually observed

served in this case to be most fatal. The exhalation of the sap from the wood of the vessel is certainly the occasion of this, and if it could be contrived to have this sap properly exhaled before the timber was used, it would not only prevent this mortality among the men, but the vessel itself would be the fonder and the better for it. Deslandes, *Trait. de Phyl.*

Woods are distinguished into divers kinds, with regard to their natures, properties, virtues, and uses. Of wood, considered according to its qualities, whether useful, curious, medicinal, &c. the principal is that called timber, used in building houses, laying floors, roofs, machines, &c. See **TIMBER.**

Woods valued on account of their curiocity are, *cedar, ebony, mahogany, walnut-tree, box, calambo, &c.* which, by reason of their extraordinary hardness, agreeable smell, or beautiful polish or grain, are made into cabinets, tables, combs, beads, &c.

The medicinal woods are, *guaiac*, which the Spaniards call *ligno santo*; *aloes*, or *agalochum*; *sassafras*, *nephriticum*, *santal*, *logwood*, *asphaltum*, *eagle-wood*, or *pan d'aquilo*, &c.

Woods used in dyeing are, the *Indian wood*, *Brazil*, *Campêche*, &c.

In extracting the colouring-matter of dye-woods, and in making some other colours for the use of calico-printers, Mr. Parkes observes (*Chem. Ess. vol. ii.*), that it is of great consequence to heat the vessels by steam; for by this method of preparing decoctions, the workmen are prevented from ever giving the materials a greater heat than that of 212° ; and the injury which was formerly done by the burning of the grosser matters at the bottom and sides of the copper is avoided. Several manufacturers, says this ingenious chemist, have now adopted this method. This leads us to take notice of a beneficial application of charcoal, as a slow conductor of caloric, for preserving an equable temperature. Ground charcoal, it is said, will conduct heat more slowly than even dry sand, in the proportion, according to Guyton, of three to two. Accordingly, all those vessels which are heated by steam, if they were made double, and the space between the inner and outer vessel filled with ground charcoal, the heat would be so prevented from escaping, that any given temperature might be maintained for a long time, and thus there would be a material saving in the article of fuel. Moreover, when churches or other large buildings are to be warmed by steam, those parts of the conducting-pipes which are not within the buildings should be always surrounded in this manner, and then no heat could escape until it had been conveyed to the space which it was intended to warm by it. Thus also in the manufactories of starch, paper, gunpowder, blue, and a variety of other articles, every part of the apparatus for drying these by steam, and which is not actually within the drying-rooms, ought to be secured in the same way. The common steam-working apparatus, and other culinary utensils, would be much improved by being fitted with double covers, and by filling up the intermediate spaces with carbonaceous matter. Moreover, by securing the conducting-pipes in this manner, buildings might be effectually warmed, and processes conducted at any distance from the boiler, as steam is the most faithful carrier of heat that can possibly be; for it cannot deposit it on any bodies that have already acquired the temperature of 212° . It is also this non-conducting property of charcoal that renders it so common, says Fourcroy, cited by Parkes, in France as a material for coating furnaces, and for confining the heat, to which use its incombustible nature adapts it in a peculiar manner, as it is the most refractory body that

is known, provided it be excluded from oxygen. Charcoal is applicable to other purposes in domestic economy; such as the preserving of animal food from taint, by covering it with a few pieces of fresh-burnt charcoal, and the recovery of it by boiling it for some minutes in water with a few ounces of such charcoal. By the same means, molasses or treacle may be deprived of its disagreeable taste, so that it might be used instead of sugar. A patent has likewise been taken out for refining sugar by means of charcoal by M. Cronstat, who required for it, of the joint body of sugar-bakers in London, a remuneration of 50,000*l.*; and Mr. Parkes apprehends, that in a small concern of this kind established in the metropolis, which manufactures double loaves of a finer quality than those of any other house, the purpose is effected by the same means. The empyreumatic flavour acquired by some brandies in distillation may be removed, says the ingenious writer now cited, by digesting them in charcoal; and common malt-vinegar, boiled on charcoal, becomes colourless, without losing its strength. Water, which in long voyages acquires a disagreeable taste and smell from long standing in the wooden casks, may be purified by filtration through ground charcoal; or it may be kept sweet in casks that have been charred within side.

For the above-mentioned purposes, the charcoal should be fresh made, or heated red-hot under a cover of sand, immediately before it is used; and the requisite quantity should be previously ascertained by experiment. In some cases, it should be used in the form of powder, having been pounded immediately from the fire, before it has been exposed to the air, and the residue should be preserved for future use in bottles closely stopped. For other uses to which charcoal is applied, see **CHARCOAL** and **CARBON.**

Wood used for fuel is required of various kinds, in regard to the various works to be performed by it.

Neri every where commends oak for the wood to be burnt in the glass-houses, as the properest wood for making a strong and durable fire with a good flame.

Imperato, on the contrary, commends ash on the same occasion; because, as he says, it gives a substantial rather than a great flame: and Camerarius deservedly commends juniper wood, as affording a lasting, strong, and sweet fire, could plenty of it be had. Among the ancients, Pliny commends light dry wood; and Plutarch, the tamarisk in particular, for making the glass-house fires; but glass-making requires so great a fire, as cannot be easily made from such wood. Nor can ash be proper, because, though it gives a good fire, it soon decays. Merret's Notes on Neri, p. 275.

If wood be burnt in the open air, the greatest part of it will be dissipated in gas. Common oak, properly charred, will lose only from $\frac{3}{4}$ ds to $\frac{1}{7}$ ths of its weight; whereas, if the same kind of wood be burnt in an open fire-place, the residuum of the combustion will not be more than about $\frac{1}{10}$ th, or $\frac{1}{15}$ th of the original weight of the wood employed. Dr. Watson says, that he obtained 22 grains of charcoal from 96 of dry oak: others have given different results. From Neumann (*Chem. vol. ii.*) we learn, that for the reduction of the metallic oxyds, the charcoal of the heavier woods, *e. g.* that of the oak and beech, is preferable; and that, for common fuel, such charcoal gives the greatest heat, and requires the most plentiful supply of air to keep it burning, while those of the lighter woods preserve a glowing heat with a much less draught of air; and that for purposes which require a steady and still fire, charcoal made from wood previously divested of its bark should be employed, as it is the cortical part which crackles and flies

WOOD.

off in sparks during combustion, which the coal of the wood itself seldom does. The charcoal of wood is said to be essential to the perfection of bar-iron; but when wood became scarce, and government restricted its use, cinders and coke were substituted for it; and thus the quality of English iron was so much debased, that Russian and Swedish iron, which is prepared by means of the coal of wood, are employed by those who work in this metal. The superiority of the iron made with charcoal is attributed by M. Hassenfratz to its combination with potassium. It was by 1 Eliz. c. 15. that it was enacted, that no oak, beech, or ash-timber, one foot square at the stub, should be converted into charcoal for making iron in any part of England or Wales, except in the county of Sussex, the weald of Kent, and certain parishes in the county of Surrey. This restriction led to the practice of making bar-iron with the coke of pit-coal, the method of preparing which was kept a secret from the generality of the trade. When Mr. Henry Horne published his "Essays on Iron and Steel," in the year 1773, he gave directions for a better method than they had before known of charring pit-coal, so as to make it a proper succedaneum for wood-charcoal in the manufacture of iron. Since that time the coke of pit-coal has come into very general use, so that the consumption of this substance is now very considerable. (See COKE.) Crayons of charcoal are best made of the willow; whereas the coals of the hard woods, such as box and guaiacum, are much harder than others, whilst the charcoal of the kernels of fruits is quite soft and friable. As a pigment, the coal of ivory, or that which is procured by burning real ivory in closed vessels, is the most intensely black, and the most beautiful. The best charcoal for use as a powder for cleaning the teeth is made from the shell of the cocoa-nut. The difference between the charcoals of animal and vegetable substances may be determined by the following test. A vegetable coal will burn on a red-hot iron into white ashes, which will be readily dissolved by sulphuric acid into a bitterish liquor; whilst the ashes of animal substances are little affected by that acid, and form with it a compound with a very different taste. (See ASHES, CARBON, CHARCOAL, and GUN-Powder.) For the method of charring wood, see TIMBER and CHARRING of Posts. This appears to have been a very ancient practice. The piles that formed the foundations of the Temple of Diana at Ephesus, not long since taken up, appeared to have been charred; and about fifty years ago some oak-stakes were found in the bed of the Thames in the very spot where Tacitus says that the Britons fixed a number of such stakes, to prevent the passage of Cæsar's army; and these stakes, which were charred to a considerable depth, had completely retained their form, and were firm at the heart. About sixty years ago one of the timbers that supported Trajan's bridge over the Danube, near Belgrade, was taken up, and the outer part, to the depth of half an inch, was found to be converted into an agate, the inner parts being slightly petrified, and the central being still perfect wood, though this timber had been in the water 1700 years. (See Kirwan's Geological Essays, cited by Parkes in his Essays, vol. ii.) Many other instances occur of wood petrified and converted, more or less, into agates of various colours. Writers on this subject have recommended the practice of charring every piece of wood before it is placed in the ground. Dr. Watson, (late bishop of Landaff,) in his "Chemical Essays," vol. iii. suggests the propriety of charring all the wood that is used in mines and subterraneous drains, and particularly that which covers troughs, through which a current of water passes, and which rot in a few years by the alternate change of wet and

dry. In this connection we may add, on the authority of Chaptal, in his "Chemistry applied to the Arts," that when old chestnut and other trees are rotted within the trunk, and threatened with speedy destruction by the progress of the carious trunk, it may be stopped by applying fire to the decayed part, so as to char the whole of the neighbouring surfaces.

WOOD, in *Gardening*, is a term used to signify the shoots or branches left in fruit-trees. See PRUNING, &c.

WOOD, an epithet applied to various sorts of weeds. See WEED.

WOOD and Bark of Trees, *Canker or Erosion of*, in *Agriculture and Gardening*, a diseased state in these parts of them. It has been stated by a late philosophical writer, that the cause seems to be an excess of alkaline and earthy matter in the descending sap, as he often found carbonate of lime on the edges of the canker in apple-trees; and that ulmin, which contains fixed alkali, is abundant in the canker of the elm. The old age of a tree, in this respect, is, it is thought, faintly analogous to the old age of animals, in which the secretions of solid bony matter are always in excess, and the tendency to ossification great.

It is suggested, that perhaps the application of a weak acid to the diseased part might be of use; or that where the tree is of great value, it might be watered occasionally. See CANKER.

WOOD, *Lignin?* in *Chemistry*, the substance which constitutes the basis of wood usually so called.

To obtain this substance in a state of purity, it is necessary to digest wood in a sufficient quantity of water and afterwards of alcohol, by which means all foreign substances soluble in these fluids will be removed; the simple *woody fibre* will thus remain, which possesses the following properties.

It is composed, in general, of longitudinal fibres easily separable from one another. These fibres, when very much subdivided, become somewhat transparent. They have no smell nor taste, and are not altered by exposure to the atmosphere.

The woody fibre is insoluble in water and alcohol. It is soluble in a weak alkaline solution without being decomposed, and may be again separated by an acid. Concentrated alkaline solutions render it brown, and decompose it, especially when assisted by heat.

When heated it becomes black without melting, exhales strong acrid fumes, and leaves a charcoal, retaining exactly the form of the original mass. When distilled in close vessels it yields an acid liquor, of a peculiar taste and smell, called the *pyroligneous acid*, and which was properly considered as a distinct acid. Fourcroy and Vauquelin, however, long ago demonstrated, that it consists of nothing but the acetic acid combined with an empyreumatic oil. (See ACETOUS and PYROLIGNEOUS Acid.) Pure acetic acid is now prepared from wood both in this country and France.

The fibre of different woods has been analysed by Gay Lussac and Thenard by means of the oxymuriate of potash. The following are the results:

	Oak.	Beech.	Mean.
Oxygen	41.78	42.73	42.25
Carbon	52.53	51.45	52.00
Hydrogen	5.69	5.82	5.75
	<hr style="width: 50%; margin: 0 auto;"/>	<hr style="width: 50%; margin: 0 auto;"/>	<hr style="width: 50%; margin: 0 auto;"/>
	100.00	100.00	100.00

Wood when burnt with a smothered flame leaves, as is well

WOOD.

well known, a quantity of charcoal behind. The following is the proportion yielded by one hundred parts of different woods, according to the experiments of Proust :

Black ash	-	-	-	25
Guaiacum	-	-	-	24
Pine	-	-	-	20
Green oak	-	-	-	20
Heart of oak	-	-	-	19
Wild ash	-	-	-	17
White ash	-	-	-	17

Count Rumford, by continuing a very moderate fire for ninety-six hours, procured much larger proportions of charcoal from different woods than were obtained in the above experiments of Proust. According to this chemist, one hundred parts of different wood yielded,

Poplar	-	-	-	43.57
Lime	-	-	-	43.59
Fir	-	-	-	44.18
Maple	-	-	-	42.23
Elm	-	-	-	43.27
Oak	-	-	-	43.00

The woody fibre, when completely burnt, always leaves a certain proportion of earthy and saline matters, which constitute the *ashes* of wood. Different woods yield very different proportions of ashes. See **ASHES** and **CHARCOAL**, where other experiments by Mr. Musket on this subject are related.

The following Table exhibits the quantity of ashes left by different woods, according to Saussure junior. Saussure has extended the investigation to herbaceous and other plants; but we have omitted these, from their not being immediately connected with the present subject. See **CARBON**.

Table of Incinerations.				Constituents of 100 Parts of Ashes.					
Names of Plants.	Ashes from 1000 Parts of the Plant.		Water from 1000 Parts of the Plant. Green.	Soluble Salts.	Earthy Phosphates	Earthy Carbonates	Silica.	Metallic Oxysds.	Loss.
	Green.	Dry.

Wood of horse-chefnut, May 10	—	35	—	9.5					

See Dr. Thomson's System of Chemistry, vol. iv. 5th edit.

Wood, *On making Bread from*. Professor Autenrieth, of Tubingen, has lately attempted to make bread from wood, and his experiments seem to have been attended with considerable success. He had been led to form the opinion that the woody fibre was only rendered unfit for food from the foreign substances usually attached to it, and from its compact aggregation. The first of these difficulties he attempted to obviate, by selecting those woods which have little taste and smell, and which consequently contain less foreign matters; such, for example, are the birch and beech, especially the birch, which was the wood he chiefly employed in his experiments.

To render wood alimentary, it is necessary to reduce it to a state of extremely minute division, or absolute powder. It also requires the repeated action of the heat of an oven, by which means it is not only better fitted for being ground, but probably also undergoes some internal change which renders it more digestible, as is evidently the case in regard to coffee. Wood prepared in this way acquires the smell and taste of corn-flour. It is, however, never white, but always yellowish. It also agrees with corn-flour in requiring the addition of some leaven, to enable it to undergo the

fermentative process, and the four leaven of corn-flour is found to answer the best. With this it makes a perfectly uniform and spongy bread, like common brown bread; and when it is thoroughly baked, and has much crust, it has a much better taste of bread than what in times of scarcity is prepared of bran and husks of corn.

To make wood-flour in perfection, the wood, after being thoroughly stripped of its bark, is to be sawed transversely into disks of about an inch in diameter. The saw-dust is to be preserved, and the disks to be beaten to fibres in a pound-mill. The fibres and saw-dust mixed together are next to be deprived of every thing harsh and bitter, and which is soluble in water, by boiling them in a large quantity of water when fuel is abundant, or by subjecting them for a longer time to the action of cold water, as by placing them in a rivulet, for example, enclosed in a sack. The whole is then to be completely dried, either by the sun or fire, and repeatedly ground in a flour-mill till it pass through the bolting-cloth.

The ground wood is next to be baked into small flat cakes, with water rendered slightly mucilaginous by the addition of some decoction of linseed, or any other similar substance. Professor Autenrieth prefers marsh-mallow roots,

of which one ounce renders eighteen quarts of water sufficiently mucilaginous, and these serve to form four pounds and a half of wood-flour into cakes. These cakes are to be baked in an oven until they are quite dry, and become of a brownish-yellow colour on the surface. After this they are to be broken to pieces, and again ground repeatedly, until the flour pass through a fine bolting-cloth, and upon the fineness of the flour does its fitness to make bread depend. The flour of a soft wood, such as birch, will be sufficiently prepared by the process as described; but the flour of a hard wood will require the steps of baking and grinding to be repeated.

That the wood thus prepared is altered in its nature and rendered soluble, is proved by the quantity of real starch that is obtained from it by the same process, by which it is separated from wheat-flour. If wood-flour tied up in fine linen be long kneaded in a vessel of water, the water is rendered milky, and deposits slowly a quantity of starch, which with boiling water forms a thick, tough, trembling, tenacious jelly, like that of wheat-starch, and it is only necessary to see this starch to be convinced that the wood-flour is soluble and nutritious. This starch cannot be ascribed to the mucilaginous matter added to the ground wood before it is baked, as the added mucilage does not amount to more than the one-hundred and forty-fifth part of the wood, whereas the wood-flour loses about half its weight by the separation of the starch. The residuum left in the linen seems to be the woody fibres unchanged, which have not been ground sufficiently fine.

Wood-flour does not ferment so readily as wheaten-flour; but professor Autenrieth found fifteen pounds of birch-wood flour, with three pounds of four wheat leaven, and two pounds of wheat-flour, mixed up with eight measures of new-milk, yielded thirty-six pounds of very good bread. The best mode of preparing it was to mix up the five pounds of wheat leaven and flour with a portion of the wood-flour and milk to a preparatory dough; let it stand for some hours in a moderately warm place to rise, and then to knead in thoroughly the rest of the wood-flour and milk. This dough is rolled out into thin cakes, allowed to stand in a warm place to rise for a longer time than wheat-flour requires, and lastly to be put into the oven and baked thoroughly.

Professor Autenrieth made many experiments upon animals, as well as upon himself and family, in order to ascertain the nutritious properties of wood-flour, in the various forms of soup, dumplings, cakes, &c.; and he found that it was not only very palatable in all these forms (especially when combined with milk or some fatty substances), but also sufficiently nutritious, and that it did not disorder the digestive organs, or apparently produce any other ill effects.

From these experiments, it is obvious, says the writer from whom we have made these extracts, that in cases of necessity wood may be made to furnish a considerable quantity of nourishment; but it is no less obvious, that the process is so troublesome and expensive, that it never can become an article of food, except where there is an absolute scarcity of provisions. On such occasions the labour is of very secondary importance, and at any rate cannot be so profitably applied as in procuring the means of subsistence.

In some districts of Norway and Lapland, the bark of the fir is manufactured into a species of bread, apparently much inferior in quality to the bread of wood-flour, and this with dried fish and a little rein-deer tallow constitute the chief articles of food among the lower classes, during the protracted and rigorous winter of these inhospitable climates. See Von Buch's Travels in Norway and Lapland.

WOOD, *Distillation of*. See CHARCOAL, COLOUR, GUN-Powder, PYROLIGNEOUS Acid, and WOOD *supra*.

WOOD, *Tenacity and Strength of*. See COHESION and STRENGTH of Materials.

WOOD and Wood, a term in ship-building, implying that when a tree-nail, &c. is driven through, its point is directly even with the inside surface, whether plank or timber.

WOOD, *Cord*, denotes wood for the fire, generally the branches or loppings of trees, piled up in order. See CORD.

WOOD, *Fossil, Subterraneous*. There are divers places where wood is found under ground: supposed to have been overturned, and buried there from the time of the Deluge, or at some other period.

Whole trees, or parts of them, are very frequently found buried in the earth, and that in different strata; sometimes in stone, but more usually in earth; and sometimes in small pieces loose among gravel. These, according to the time they have lain in the earth, or the matter they have lain among and in the way of, are found differently altered from their original state; some of them having suffered very little change, and others being so highly impregnated with crystalline, sparry, pyritical, or other extraneous matter, as to appear mere masses of stone or lumps of the common matter of the pyrites, &c. of the dimensions, and more or less of the internal figure of the vegetable bodies, into the pores of which they have made their way.

The fossil wood, which we find at this day, may, according to these differences, be ranged into three kinds: 1. The less altered. 2. The pyritical. And, 3. The petrified.

Of the trees or parts of them less altered from their original state, the greatest store is found in digging to small depths in bogs, and among what is called peat or turf-earth, a substance used in many parts of the kingdom for fuel. In some places there are whole trees scarcely altered except in colour; the oaks in particular being usually turned to a jetty black: the pines and firs remain as inflammable as ever, and often contain between the bark and wood a plain resin. Parts of trees have been also found unaltered in the strata of clay and loam, among gravel, and sometimes even in solid stone. See Fossil PLANTS, and Bog WOOD.

It is idle to imagine, that these have been thus buried either at the Creation, or, as many are fond of believing, at the universal Deluge: at the first of these times the strata must have been formed before trees were yet in being, and the peat wood is so far from being of antediluvian date, that much of it is well known to have been growing within these three hundred years, in the very places where it is now found buried. See MORASS.

The substances that are more altered are the larger and longer branches of trees found bedded in the strata of stone, and partly assuming its nature; and the shorter and smaller branches found in pits of blue clay, which externally bear the resemblance of what they once were, but, having their pores filled with the matter of the common vitriolic pyrites, internally appear to be masses of that matter.

The irregular masses or fragments of wood are principally of oak, and most usually found among gravel, but variously altered by the insinuation of crystalline and strong particles. These make a beautiful figure when cut and polished, as they commonly keep the regular grain of the wood, and shew the several circles which mark the different years growth. These, according to the different matter which has filled their pores, assume various colours, and the appearance of the various fossils that have impregnated them. Of these some pieces have been found with every pore filled with

with pure pellucid crystal, and others in large masses, part of which is wholly petrified, and some mere stone, while the rest is crumbly and unaltered wood.

All these pieces of petrified wood are usually capable of a high and elegant polish. Hill.

Wood has been found in salt-mines, inclosed in a mass of hard salt, and its pores filled with the matter of the salt in which it lay. Wood has likewise been found converted as it were into iron, or thoroughly impregnated with the particles of this metal. Aët. Erud. ann. 1710.

Wood, *Petrified*. The opinions of the judicious part of the world have been very different in regard to the bodies preserved in the cabinets of the curious, under the name of petrified wood; some affirming these bodies to have been only pebbles, or flints accidentally formed in this shape, and with veins resembling those of the wood; and others affirming with equal warmth, that they have been really wood, into which stony matter has been brought by water.

Many substances, it is certain, have been preserved in the cabinets of collectors, under the title of petrified wood, which have very little right to that name. But where the whole outer figure of the wood, the exact lineaments of the bark, or the fibrose and fistular texture of the stræ, and the vestiges of the utriculi and trachææ or air-vessels are yet remaining, and the several circles yet visible, which denoted the several years growth of the tree, none can deny such substances to be real fossil wood.

Many good arguments have been produced on both sides the question, but M. De la Hire has attempted to bring the dispute to a certain conclusion, by means of some peculiarly happy specimens, which were of the palm-tree petrified, found in the deserts of Africa: these on comparing them with pieces of the palm-tree cut out of the recent wood, appeared to have every where the beautiful and regular veins of that wood, and left no room to doubt but that they certainly had been once the vegetating wood of that tree, though now converted into hard stone; the petrified pieces were perfect stone, in all its qualities; they had its hardness, its sound when struck upon, and were, as many other stones are, opaque in some places, and transparent in others; they were found on weighing them to be often of the specific gravity of recent pieces of the palm wood of the same dimensions.

Father Duchat also, an author of unquestioned credit, affirms, from his own personal knowledge, that in the kingdom of Ava there is a river whose waters petrify recent wood into flint; and that he has often seen trees standing in it, whose bottom part, so far as covered with the water, has been true flint, while all above was mere dry wood, and fit for firing. Mem. Acad. Par. 1692.

Wood, *Shining*. There are a great many things in which a piece of rotten wood that shines in the dark agrees with a burning coal; and there are also many things in which they differ. They agree in these particulars: 1. They have light residing in them, and are not like bodies which are only luminous according to the quantity of light which falls upon them from other bodies, and which they reflect. 2. Both shining wood and burning coals require the presence of the air to keep them shining, and both require also an air of a considerable density; and both having been deprived of their shining quality by the pumping out of the air, will recover it again on the admitting of fresh air to them. 3. Both of them will easily be quenched by putting them into water, and many other liquors. And, 4. As a live coal will not be extinguished by any coldness of the

air, neither will the shining wood be deprived of its light on any additional coldness in that element.

However, they differ in the following particulars: 1. A burning coal is easily put out by compression, the treading on it and squeezing it together readily divesting it of its light; on the other hand, compression or crushing of any kind seems not to have any effect upon the shining wood; its bruised parts shining as brightly as its entire ones. If a piece of this shining wood be squeezed between two glasses, this experiment will be most fairly tried; and in this case, though the contexture of the whole be evidently broken, and the parts separated, the light is as strong in them as while the piece was entire. 2. A burning coal extinguished by the drawing out of the air will, after a few minutes, be irrecoverable, on the admission of air in any manner; but, on the contrary, the shining wood, when thus extinguished and kept extinct for half an hour, will be immediately re-kindled on admitting the air to it. 3. A live coal, included in a small glass, will continue shining but a few minutes; but a piece of shining wood, in the same circumstances, will continue bright for several days. 4. The coal, while it burns, sends forth smoke and other exhalations; the rotten wood sends out none, and consequently a coal all the while that it is shining wastes itself at a great rate; but the rotten wood does not waste itself at all. And finally, the burning coal is actually and vehemently hot; the rotten wood, though it shines, is not so much as warm. Phil. Transf. N^o 32.

The light of shining flesh and fish, when putrefied, is wholly of the same nature with that of rotten wood, as to its dependence on the air for its splendour; and in the same manner loses its light in the exhausted receiver, and regains it on the admission of the air into it again, in the same sudden manner. Phil. Transf. N^o 31. See LIGHT, and PUTREFACTION.

WOOD, *Bog*, or *Subterraneous*, a name given by the inhabitants of many parts of this kingdom to such wood as is found buried in the earth in boggy places, and which is found hard and strong at this time. See Fossil WOOD *supra*.

We have in the Philosophical Transactions (N^o 275. p. 983, &c.) an account of vast quantities of this sort of wood found under ground in Hatfield Chase. Many of the roots and bodies of trees are found there; which are of all growths, and are mostly such trees as are the growth of our own soil, such as oaks, firs, birch, beech, yew, holly, willow, ash, and the like. The roots of all these trees stand in their natural positions as when growing, and stand as thick together as they could grow in a forest. The bodies are usually broken off, and laid all along just by them.

The large trees are usually found fallen in a north-east direction, and the smaller ones lying all ways; the fir-tree or pitch-tree is more common than any other kind, and is found sometimes of twenty, thirty, and thirty-five yards long, and so found and firm that many of them have been sold to make masts for ships. Oaks have been found of the same length, though wanting some yards of their natural tops; these have been sold at ten or fifteen pounds a piece, and are as black as ebony, and very sound and lasting in whatever service they are put to. The ash-trees do not preserve their firmness in this manner, many of them are so soft that the workman's spade cuts through them; and when exposed to the air, they usually fall to pieces; but the willows, though a much softer wood than the ash, preserve their texture, and are found very strong and firm. In some of the fir-trees it is very observable, that they have shot out-

outside branches after they were fallen, which have grown into large trees. Many of these fossil-trees appear plainly to have been burnt; the fir-trees are particularly very common in this state: and of these some are burnt quite through, others only on one side. Some of these also have been found with the plain marks of human work upon them; many with their branches chopt off, and their trunks cut into two or three pieces. Some squared and others in part cleft, and the wooden wedges used in cleaving them are still found remaining in the cracks. Stones are found in some of them in the place of wooden wedges, but in none iron ones. The heads of axes are also sometimes found; they are of a strange form, and somewhat represent the sacrificing axes of the ancients. These are found at such depths, that it is impossible they should have ever been lodged there since the time of this place's being a forest; nor ever could have been found, but by means of the ground's being drained by a late invention. The general opinion as to these trees is, that they were buried in this manner at the time of the universal Deluge; but they are plainly of later origin as fossils, the coins of some of the Roman emperors having been found buried under them.

The earth of bogs is not the only soil that preserves these trees; for in the low parts of Lincolnshire, between the towns of Burningham and Brumley, there are several large hills composed only of loose sand, and as this blows away there are continually discovered whole trees, or parts of trees, and particularly the roots and stumps of firs, and some other kinds, all with the marks of the axe upon them, and looking as fresh as if done but yesterday. Under these hills, and in the bogs before-mentioned, not only the wood of the fir-tree, but its cones are found in immense number; many buhels being often laid in a heap together. In cutting a drain for a river of a considerable depth, there were found at the very bottom several parcels of cut wood, in poles, beams, and the like; the head of an axe was also found somewhat resembling the ancient battle-axe, and a coin of the Roman emperor Vespasian; but what was yet more remarkable was, that what they were now sunk to seemed to be the original surface, the ground not being loose, like all above it, but found and firm, and lying in ridges and furrows, with the evident marks of having formerly been ploughed. So that all the bog-earth above seems plainly to have been added since; and that the fossil wood, supposed of antediluvian origin, is but of the time of the ancient Romans, or less than that.

All the bogs in this kingdom afford in like manner fossil-trees; and not only those, but other places, have at all times accidentally discovered them. Giraldus Cambrensis tells us, that so long since as in king Henry the Second's time, the sands on the shores of Pembrokeshire were driven off by peculiar storms and tempests, and that deep under those sands there were then discovered great numbers of the roots and bodies of trees in their natural postures; and many of these had the strokes of the axe upon them, the marks at that time remaining as plain as when first made. Some of these resembled ebony; and many other such trees were discovered at Neugall in the same county, in the year 1590. Camden tells us of such wood found in the bogs in Somersetshire, Cheshire, Lancashire, Westmoreland, Yorkshire, Staffordshire, and Lincolnshire; and since his time many other counties have been found to be as fruitful in it. Dr. Plot mentions them in many parts of his History of Staffordshire, and by their standing in their natural postures, as to the roots at least, properly concludes, that they certainly once grew there, and were not brought from elsewhere.

Dr. Leigh, in his History of Lancashire, gives an account of the same sort of trees found in the draining of the boggy lands at Martin-Meer; and determines them not to have been of the ancient date many pretend, in referring them to the Deluge.

He observes, that they are plainly of no older date than the time of the savage inhabitants of England, about the time of the Roman conquests; for in this place, beside the roots and bodies of trees and their fruit, there were found eight canoes, or small boats, such as the wild inhabitants used at that time. And in another moor in the same county, a brass kettle, with a small mill-stone, and some beads of wrought amber. In the same place were also found several human bodies whole and entire, at least to outward appearance, and the whole head of an hippopotamus, or river-horse. This is perhaps the hardest thing to be accounted for of the whole set, as to its coming there. The boggy places, in Anglesea, and the Isle of Man, are all full of buried trees of the same kind; and the bogs of Ireland abound no less with them. England, and its adjacent islands, are not the only places where this buried wood is found; for Vertegan tells us, that the moors in the Netherlands abound with them; they all lie north-east, as our's do. Helmont also mentions the Peel there, a morass of eight or nine miles broad, which is full of them. The French naturalists tell us of fossil-trees also in their country; and in Switzerland and Savoy; but all in the low grounds.

Ramazzeni tells us, that in the territories of Modena, which are now a dry and fruitful country, yet in the time of the Cæsars were only a great lake, there are found at the depth of thirty, forty, and even fifty feet, the soil of a low marshy country, with sedges, water-grass, and other marsh-weeds; and under this there lie the trunks of trees, and their roots stand near them in as natural a posture as when growing. Many old coins of the Roman emperors are also found there; as also several busts, wrought marble, and squared stones, evidently shewing the work of such tools as the Romans have been known to use. Some of the trees in these places stand upright. See more on this subject under the article MORASS.

WOOD, *Cutting of.* See CUTTING.

WOOD, *Measure of.* See MEASURE.

WOOD, *Stack of.* See STACK.

WOOD, *Staining of.* See DYEING of Wood, &c.

Wood may be stained yellow, by brushing it over several times with the tincture of turmeric root, made by putting an ounce of the powdered root to a pint of spirit, and after it has stood some days, straining off the tincture. A redder cast may be given to the colour by adding a little dragon's blood. A cheaper, and less bright and strong yellow may be given to wood by rubbing it over several times with the tincture of French berries, made boiling hot; and when the wood is dry, brushing it over with a weak alum-water used cold.

In order to render these stains more beautiful and durable, the wood should be brushed after it is coloured, and then varnished with the seed-lac varnish, or with three or four coats of shell-lac varnish.

For a bright red stain for wood, make a strong infusion of Brasil in stale urine, or water impregnated with pearl-ashes in the proportion of an ounce to a gallon; to a gallon of either of which add a pound of the Brasil wood. With this infusion, after it has stood, with frequent stirring, two or three days, strained and made boiling hot, brush the wood over till it appears strongly coloured; and while it is wet, brush it over with alum-

water made in the proportion of two ounces of alum to a quart of water.

For a less bright red, brush over the wood with a tincture made by dissolving an ounce of dragon's blood in a pint of spirit of wine.

For a pink or rose red, add to a gallon of the above infusion of Brasil wood two ounces of pearl-ashes, and use it as before: observing to brush the wood over often with the alum-water. These reds may be varnished as the yellows.

Wood may be stained blue by means either of copper or indigo. The brighter blue may be obtained by brushing a solution of copper (see VERDITER), while hot, several times over the wood: and then brushing a solution of pearl-ashes in the proportion of two ounces to a pint of water hot over the wood. It is stained blue with indigo, by brushing it with the indigo prepared with soap-lees as when used by the dyers, boiling hot; and then with a solution of white tartar or cream of tartar, made by boiling three ounces of either in a quart of water, brushing over the wood plentifully before the tincture of indigo be quite dry. These blues may be brushed and varnished as the reds, if necessary.

Wood may be stained green by dissolving verdigrise in vinegar, or the crystals of verdigrise in water, and with the hot solution brushing over the wood till it be duly stained.

A light red-brown mahogany colour may be given to wood by means of a decoction of madder and fustic wood, ground in water, in the proportion of half a pound of madder and a quarter of a pound of fustic to a gallon, or, instead of the fustic, an ounce of the yellow berries may be used. Brush over the wood with this solution, while boiling hot, till the due colour be obtained. The same effect may to a considerable degree be produced by the tincture of dragon's blood and turmeric root, in spirit of wine.

For the dark mahogany, take the infusion of madder as above, and substitute for the fustic two ounces of logwood: and when the wood has been brushed over several times, and is dry, brush it over slightly with water in which pearl-ashes have been dissolved, in the proportion of about a quarter of an ounce to a quart. The wood, in the better kind of work, should be afterwards varnished with three or four coats of seed-lac varnish; but for coarse work, with the varnish of resin and seed-lac, or they may be well rubbed over with drying oil.

Wood may be stained purple by brushing it over several times with a strong decoction of logwood and Brasil, made in the proportion of one pound of the logwood and a quarter of a pound of the Brasil, to a gallon of water, and boiled for one hour or more. Let the wood, well coloured, dry, and be then slightly passed over by a solution of one drachm of pearl-ashes in a quart of water. A solution of gold in spirit of salt or aqua regia will give a durable purple stain to wood.

For a deep black the wood is brushed over four or five times with a warm decoction of logwood, made as above without the Brasil, and afterwards as often with a decoction of galls, made by putting a quarter of a pound of powdered galls to two quarts of water, allowing it to dry thoroughly between the several applications of the liquors: thus prepared, it receives a fine deep black colour, from being washed over with a solution of vitriol in the proportion of two ounces to a quart: in the room of which some use a solution of iron in vinegar, keeping the vine-

gar for this purpose upon a quantity of the filings of the metal, and pouring off a little as it is wanted. A pretty good black is also obtained, more expeditiously, by brushing over the wood, first with the logwood liquor, and afterwards with common ink.

A very fine black may be produced by brushing the wood several times over with a solution of copper in aqua fortis, and afterwards with the decoction of logwood, repeated till the colour be of sufficient force, and the greenness produced by the copper overcome. The blacks may be varnished as the other colours.

Where the stains are desired to be very strong, as in the case of wood used for fineering, it is generally necessary it should be soaked, and not brushed; for which purpose the wood may be cut into pieces of a proper thickness for inlaying. Lewis's Phil. Com. Techn. p. 97. 434. Handmaid to the Arts, vol. i. p. 508, &c.

WOOD, *Engraving on*. See WOOD-ENGRAVING, *infra*.

WOOD, *Painting on*. See PAINTING.

WOOD, *Sculpture in*. See SCULPTURE.

WOOD, *Sylva*, in *Geography*, a multitude of trees, extended over a large continued tract of land, and propagated by nature, or without culture.

Many great woods only consist of trees of one kind. At Cape Verd, in Africa, are woods of orange and lemon trees; in Ceylon, are woods of cinnamon-trees; in the Molucca islands, woods of clove-trees; in the islands of Nero, Lontour, Lofgain, &c. woods of nutmeg-trees; in Brasil, woods of Brasil-trees, &c.; in Numidia, woods of date-trees; in Madagafcar, woods of tamarind-trees, &c.

WOOD-*Ashes*, in *Agriculture*, the ashes which are formed by burning wood.

The ashes of some sorts of wood, too, are found to be more powerful as a manure than those of others, as those from the ash and some other such trees.

It is said by some that they are an excellent dressing for improving cold wet pasture land; and that poor hungry pastures have been very profitably benefited by them, to near double their former value; that nothing equals them on low spongy pasture land. Others, however, have tried them on grass-lands with little or no effect.

The difference in the burning and forming of them may probably cause this difference in the effects which they have on land.

WOOD-*Bound*, a term used to signify such land as is encumbered with tall woody hedge-rows, so as to prevent the free circulation of air and admission of the sun, by which the natural fertility and strength of it cannot be fully exerted or brought into action. See WOOD-LAND.

WOOD-*Coppices*. In the first raising of coppices, two things are to be considered; first, the nature of the soil, that such trees may be planted in it as will thrive well there; and secondly, the uses that the wood is intended to be sold for, that such kinds may be planted as will be most proper for those uses.

If the principal vent for wood be for the fire, the best trees for fire-wood must be planted, such as the oak, beech, hornbeam, or other hard wood. These are the most profitable for felling as fire-wood, and one or more of these grow in any soil.

If there be a demand in the country where the coppice is to be planted for hoops and hop-poles, then the ash, the chestnut, the oak, alder, and hazel, are to be planted.

According

According to the profits of the underwood, the thickness of the standard-trees is to be regulated; for as they stand more or less thick, they more or less injure the underwood. It is also to be considered at what growth the underwood is to be sold. The taller and larger the underwood of a coppice in general is, the more profitable will it be for firing, and all other uses, and the standards will be the better for its being left to grow to a proper height, for their bodies will be always, unless very great accidents occur, carried up straight as far as they are shaded by the coppice-wood.

A deep soil makes the shrubs as well as trees grow more vigorously than any other, and they will be sooner fit for cutting in such places. The person who owns these woods must contrive to cut down only a certain quantity of them every year, and regulate this so that he may have a constant succession of a like quantity; that part of the wood which was at first felled, may be grown up to its size for felling again by the time the last is cut. This is, in different places, to be calculated to all the various numbers between eight years and twenty or thirty.

The cutting of wood seldom yields the more and the better timber; but the cutting of it oftener has greater advantages, in that it makes it grow thicker, and gives the seedlings time to come up. If many timber-trees grow in the coppice, and are to be cut down, they and the underwood should be felled together, cutting off the stumps as close to the ground as may be, in the trees, and in the shrubs and underwood the stumps should be left about half a foot high, and cut slanting and very smooth.

Sawing is the best method of felling timber-trees; but it sometimes kills the root; and if this is observed to be the case in the coppice, no new shoots arising from the root, then it is proper to stub up the root, that it may not unnecessarily encumber the ground, and that the other young plants may have the benefit of it.

In the first raising of coppices from seed, the ground must be prepared by good tillage, as much as if it were intended for corn. The seeds of the several trees are to be sown in February, and if the soil be shallow, the ground should be ploughed into great ridges: this will make the soil lie the thicker upon the top of each ridge, by which means the roots will have more depth to run to for nourishment, and in a few years the furrow will be filled up to the level of the rest with the dead leaves; and these, as they rot at the bottom, will make a kind of soil, through which the young shoots will spread, and be conducted from one ridge to another, and so the whole ground will be occupied by them. If the coppice be to be raised on the side of a hill, plough the ridges cross-way of the descent of the hill, that the water may be detained among them, and not suffered to run off, as it otherwise would by the furrows; but if it happen that the ground be over-wet, which is more rarely the case, then the contrary method is to be observed, and the furrows ploughed deep and straight downwards, that all water may be carried off by them, as by so many trenches or drains.

Some sow a crop of corn along with the seeds of the underwood, for the advantage of the first year; but as the season of sowing the seeds of the trees is too late for the sowing of the corn, it seldom turns to much advantage. It is better to sow the trees alone, and keep them well weeded the two first years; after which they are strong enough to take care of themselves against such enemies.

In very barren ground, where the young trees can hardly stand the heat in summer, it is proper, after sowing

them, to scatter a quantity of furze-feed over the land; the furze will grow quick, and over-top the trees at first, but it will serve as a guard to them at this time, defending them from injuries, and keeping the ground moist about their roots. In a few years the trees will grow up beyond these bushes, and they will then soon destroy them by their dropping.

In the raising of coppices, the nearest distance for the plantations ought to be five feet for the underwood, but as to what number, and scantlings of timber are to be left on each acre, the statutes in this case direct; but it is an ordinary coppice, which will not afford three or four firsts, fourteen seconds, twelve thirds, and eight wavers, according to which proportion the sizes of young trees in coppices are to succeed one another. In coppice or underwood felled at twenty-four years growth, there are to be left twelve store-oaks upon every acre, or, in defect of them, the same number of elms, beech, or ash: these are to be straight-bodied trees, and are to be left till they are ten inches in diameter, at a yard from the ground; but it is better for the owner to have a much greater number of timber-trees, especially in places where underwood is cheap; and as to the felling, it is always necessary to begin regularly with one side, that the carriages, necessary to the taking off the wood, may come on without injury to the rest: and in large woods, a cart-way should always be left in the middle, quite through the wood. The timber of the underwood may be cut from the month of October to February; but the last month is much the best, in places where there is but a small quantity to be felled, and it can all be got down before the spring is too much advanced. All the wood should be carried out by Midsummer, and made up by April at the latest; for when the rows and brush lie longer than this unmade up, and unbound, many of the shoots and seedlings are spoiled by them. It is always worth the owner's while to inclose the coppice well the winter before felling, to keep out the cattle, which would else greatly damage the supply from the seedlings and young shoots.

New-weaned calves are the least prejudicial to newly cut woods of any creatures, and may be put in where there is much grass; the next in harmlessness to these are young colts, which, at about a year old, may be put in to feed in the same manner; but about May they must all be put out.

If the woods happen to be cropped by cattle, it is best to cut them up, and they will make new shoots; for that which has been bitten by the cattle will not grow for several years in any degree.

If the coppice-woods are too thin, this is to be remedied by laying down the longest and smallest shoots of those shrubs or trees which are the most advantageous, in the place, or of such as are nearest the bare place; these will each send forth a great number of suckers, and the whole wood will be thickened as much as desired in a very little time. Mortimer's Husbandry, vol. ii. p. 64. See COPPICE.

WOOD, *Almiggim*. See ALMIGGIM.

WOOD *Anemone*. See ANEMONE.

WOOD-*Bine*, or *Wood-bind*, in *Botany*, a species of *lonicera*; which see.

WOOD-*Bind*, *Spanish*, a species of *ipomoea*; which see.

WOOD-*Chat*, in *Ornithology*, *lanius minor primus* of *Aldrovandus*, a species of butcher-bird, with a horn-coloured bill; the feathers at the base are whitish; above is a black

black line drawn across the eyes, and then downwards on each side the neck; the head and hind part of the neck are of a bright bay; the upper part of the back dusky; the coverts of the tail grey; the scapulars white; the coverts of the wings dusky; the quill-feathers black, having a white spot at the bottom; the throat, breast, and belly of a yellowish-white; the legs black. In the female, the upper part of the head, neck, and body, are reddish, striated transversely with brown; the lower parts of the body are of a dirty white, rayed with brown; the tail of a reddish-brown, marked near the end with dusky, and tipped with red. Pennant.

Wood-Cock, Scolopax rusticola of Linnæus, called by other writers *la becaffe*, a well-known bird distinguished by its size, which is somewhat smaller than that of the partridge, and by its colour, which is on the back a variegation of black, grey, and a reddish-brown; on the forehead the black predominates; the quill-feathers are dusky, indented with red marks; and on the belly a pale grey, variegated with transverse streaks of brown. Its beak is three inches long, dusky toward the end, and reddish at the base, and the upper chap a little longer than the under: the tongue slender, long, sharp, and hard at the point; the eyes large, and placed near the top of the head, that they may not be injured when the bird thrusts its bill into the ground: from the bill to the eyes is a black line; the forehead is a reddish ash-colour; the chin is of a pale yellow; the tail consists of twelve feathers, dusky or black on the one web, and marked with red on the other; the tips above are ash-coloured, below white: the legs and toes are livid, the latter divided almost to their origin, having only a very small web between the middle and interior toes.

These birds, during summer, are inhabitants of the Alps, Norway, Sweden, Polish Prussia, the Mark of Brandenburg, and the northern parts of Europe; whence they emigrate at the approach of winter into milder climates, where the ground is open and adapted to their manner of feeding. The time of their appearance and disappearance in Sweden coincides exactly with that of their retreat from and arrival in Great Britain. They live on worms and insects, which they search for with their long bills in soft ground and moist woods. They generally arrive here in flocks, taking advantage of the night or a mist; they soon separate: but before they return to their native haunts, pair. They feed and fly by night; beginning their flight in the evening, and returning the same way to their day-retreat.

They leave England the latter end of February, or beginning of March; though they have been known to continue here accidentally. In Casewood, near Tunbridge, a few breed almost annually. During incubation they are very tame. They come over to the coast of Suffolk sparingly in the first week of October, the greater number not arriving till the months of November and December, and always after sun-set. They are determined in their flight by the wind, and arrive separate and dispersed. When the red-wing appears on the coast in autumn, the wood-cocks are at hand; and when the Royston crow is arrived, they are come. Between the 12th and 25th of March they flock towards the coast to be ready for their departure, having the red-wings for their harbingers in spring, as in autumn. If the wind be favourable, they immediately depart; but otherwise, they are detained in the neighbouring woods, or among the ling and furze on the coast: as soon as a fair wind springs up, they are suddenly gone.

In the same manner they are known to quit France, Germany, and Italy; making the northern and cold situations their general summer rendezvous. In the winter they are found as far south as Smyrna and Aleppo, and also in Barbary; and some have appeared as far south as Egypt, which seems to be the limit of their migration in that way. In Japan they are found very common. Those that resort into the countries of the Levant probably come from the deserts of Siberia or Tartary, or the cold mountains of Armenia.

Our species of wood-cock is unknown in North America; but they have a sort of wood-cock resembling ours in its general appearance; about half its size, and wanting the bars on the breast and belly. Pennant.

They hate flying high, and they are afraid to fly among trees, because, like the hare, they see but very badly straight before them; and it is owing to this imperfection in their sight, that they are so easily taken in nets spread in their places of resort.

The draw-net, in countries which are very woody, is extremely profitable in this sport, it being no uncommon thing to take ten or a dozen wood-cocks at a time in it.

There is another method of taking these birds in high woods, with those nets called *hays*, of the nature of the rabbit-hays, only with smaller meshes. The wood-cocks are to be driven into these, and there should always be at least two or three of them planted together. When the sportsman has provided himself with nets, he is to take five or six persons into the wood with him. The proper woods for this purpose are those of seven or eight years' growth; and the people are to go into some part of them near the middle. The nets or hays are to be placed in the same manner as they are for taking of rabbits, but two or three joining together at the end, and hanging over slopewise that way which the wood-cocks are intended to be driven.

The nets being thus fixed, let the company go to the end of the wood, placing themselves at about ten rods distance from one another; they must all have sticks in their hands, and they are to move forward slowly towards the nets, making a noise by striking the sticks against the trees and branches, and by hallooing with their voices: in this manner they are to move up to the net; and the wood-cocks in that part of the wood will all be terrified before them, but will not take wing, but run along upon the ground, and thus be driven along like a drove of beasts, so that when the company come up, they will find almost all of them in the net. When that part of the wood is thus driven, the nets are to be turned the other way, and placed slopewise in the contrary direction, and the company retiring to the other end of the wood, are to drive the wood-cocks that are in that part with the same noise, till they have sent them into the nets in the same manner.

Thus all the wood-cocks in the wood may be taken with very little trouble, and this may be done equally at any time of the day.

Another way of taking this bird is by means of noozes or springs.

The wood-cock and the snipe are both easily taken with bird-lime, when their places of resort are known, but they are not so easily found as many other birds.

The custom of the wood-cock is usually to be upon the banks under hedges, and by the sides of ditches toward the sun; and they will suffer the sportsmen to come nearer them in the day-time after a moon-shiny night, than after a dark one. The reason of which is, that having fed well by moon-light, they are only fit for rest the day following;

but

but when the night has been dark, they are seeking food all day long.

The snipes naturally lie by the sides of rivers, when the plashes and ponds are frozen, and they always lie with their heads up or down the stream, never transversely.

In order to take either of these birds by bird-lime, the sportsman must be provided with a large number of small and smooth twigs, neatly and evenly covered with good bird-lime. These must be placed sloping, some one way, some another, and the whole place about where they resort must be covered with them. The sportsman then must conceal himself very carefully, that the sight of him may not frighten away the game. See *COCK-ROAD*.

WOOD-COCK Apple, in *Rural Economy*, a fine cyder fruit. See *APPLE-Tree*.

WOOD-COCK Shell, a name given by the English naturalists to a peculiar kind of the purpura. It is called in French, *becasse*, from the length of its beak. There are two species of this, a prickly and a smooth one.

The prickly kind is an extremely beautiful and elegant shell. It is of a yellowish colour; and its tail or beak (for the hinder extremity of the shell, which runs out into an immoderate length, is sometimes called by the one, sometimes by the other of these names) is furnished with four rows of large and very long spines: between the rows of these, there are also rows of small and short spines. The body of the shell is furrowed very deep, with a number of transverse circular lines; and both this and the clavicle are beset with several rows of long spines.

The smooth *becasse*, or wood-cock shell, is a very elegant species, but much less so than the other. It is of a yellowish colour, radiated with black and grey lines. It is all over deeply furrowed, and the ridges are beset with tubercles, the clavicle is elevated, and the tail extremely long, and hollowed into a sort of tube. The mouth of this, as well as of the other, is small and roundish, and in this species is of a light flesh-colour.

WOOD-COCK Soil, in *Agriculture*, a term applied to such land as has the mould of a dapple-brownish colour, and which is said not to be of a good quality for many purposes. See *SOIL*.

WOOD-CORN is a certain quantity of oats, or other grain, anciently given by customary tenants to their lord, for the liberty to pick up dead or broken wood.

WOOD-EVIL, or *Cramp in the Legs*, a disease among sheep, which is so named in consequence of its being supposed in general to arise from the drippings of trees in cold and wet weather. It shews itself by seizing the legs of the sheep, and making them totally incapable of walking; and will sometimes all at once spread through the whole flock.

In regard to the means of cure, a tea-spoonful of the flour of mustard has been advised to be given every night and morning. The affected parts should also be well rubbed with warm flannel, and the sheep be kept dry, which are very effectual aids. The use of a little oil of turpentine externally may often also be advantageous, where the other mode of rubbing does not succeed: and in bad cases the use of mild mercurials with opium may be had recourse to with much benefit.

WOOD-FUEL, Saw for cutting of, in *Rural Economy*, a tool used for this purpose. On the continent they employ an improved instrument of this kind, the iron part of which consists of a saw, three inches in breadth, and sixteen inches in length, double toothed, in the manner of the gardener's pocket saw, and fixed in a frame of tough ash-wood, as below. The edge part of the saw is made broader than the

back, in order that it may work more freely and with greater ease.

The frame of the saw at the top part has a strong cord tied round each side of it, so as to tighten the saw and keep it from bending, being capable of being twisted tighter by a small thin piece of wood put between the double cord, and which may be kept from untwisting by being rested against the cross-bar in the upper part, which is mortised and firmly fastened into the two side pieces, being the only means that keeps the frame together in a safe manner. The side pieces are each twelve inches in length; and the additional length of the handle part of one of them five inches. It is evident that this saw will, on the principle of lessening friction, and of keeping the cutting part from bending, work with much greater facility and expedition than the common carpenter's saw.

With this wood-saw twice as much work may be done in a day as with the common hand-saw that is in general use in this country.

WOOD-GELD, Woodgeldum, in our ancient customs, the gathering or cutting of wood within the forest. Or it may denote the money paid for the same to the foresters. Sometimes it also seems to signify an immunity from this payment, by the king's grant. Crompton says expressly, it signifies to be free from the payment of money for taking of wood in a forest. See *GELD*.

WOOD-HAY, an ancient custom at Exeter; by which a log out of every seam of wood brought over Ex-bridge is taken towards the reparation of that bridge. *Antiq. of Exeter*.

WOOD-LAND, in *Agriculture*, a term used by the farmers of many counties of England for a sort of soil, from its constant humidity and dark colour, resembling the soil in woods, which, of whatever nature it originally is, will always be made to appear thus from the continual dropping of trees, and the want of a free air and sun, together with the fall of leaves, destroyed and washed to pieces by the wet.

This soil in the open countries has a considerable quantity of clay in it, and holds the water a long time that once falls upon it: in wet weather it sticks firmly to the plough-share, and in dry is very apt to crack. In uncultivated places it usually produces rushes and rush-grafs. A moist and dripping year is extremely detrimental to this sort of land.

As to the clearing of wood-land in order to bring it into a state of cultivation and improvement, the first step is that of properly digging out the roots of whatever sorts they may be, after the wood has been cut off, to prepare the ground for the operation of the plough, without mixing the under stratum of the land with the fertile surface mouldy layer of earth. The hollows and pits are then to be filled and levelled.

In some instances it may be beneficial to encourage and promote the sward and herbage by sowing over the surface suitable grass-seeds, after it has been broken and spread over with the collected and decayed or burnt woody and leafy matters, stocking the land hard with sheep, and mowing off occasionally the wood-shoots that may arise; thus keeping the whole in a state of close pasturage, until the smaller root parts that may have been left in the land become sufficiently decayed, to render them obedient to the plough, when the land may be broken up for corn. The use of lime and calcareous substances in mixture with these matters, or spread alone over the land, would also serve to encourage the finer sorts of herbage, the delight of sheep; and, of course, induce them to eat the grass more close, and

and bring the land sooner into the state of a thick set sward, the productive matrix of corn-crops.

WOOD-Lark, in *Ornithology*. See **WOOD-LARK**.

WOOD-Layer, in *Agriculture*, a term used to signify the young oak or other timber plants which are laid down into hedges, among the white thorn or other plants used in fences. See **HEDGE**.

WOOD of Life, in *Botany*. See **GUAIAACUM**.

WOOD-Lock, in *Ship-Building*, a piece of elm, closely fitted and sheathed with copper, in the throating or score of the pintle, near the load-water-line; so that when the rudder is hung, and the wood-lock nailed in its place, it cannot rise, because the latter butts against the underside of the brace and butt of the score.

WOOD-Louse. See **MILLEPEDES**.

WOOD-Meil, a coarse, hairy kind of stuff, made of Iceland wool, with which the ship-carpenters, in some of his majesty's yards, line the ports of ships of war.

WOOD-Mite, in *Natural History*, the name of a little animal frequently made the subject of microscopical observations, and by some called the *wood-louse*; though that less properly, as there is another larger animal generally known by that name.

The wood-mite is in shape and colour very like a louse, and is frequently found running very nimbly, but always by starts and jumps, on old books and rotten wood. The eyes of this creature are of a fine gold colour, and can be thrust out or drawn in at pleasure; and when examined by the microscope the peristaltic motion of the guts is seen very distinctly, and beautifully; and what is more wonderful, there is observed a very distinct and regular motion in the brain.

This probably is the same animal with the *pediculus pulforius*, described by Dr. Derham, as one of the death watches. Baker's *Microscope*, p. 185.

WOOD-Men, certain forest-officers appointed to take care of the king's woods.

WOOD-Mote, the ancient name of that forest-court, now called the court of attachment.

WOOD-Pecker, in *Ornithology*, the English name of some species of *picus*.

The green wood-pecker, *picus viridis* of Linnæus, called also the rain-fowl and pluvialis avis, weighs about six ounces and a half, is thirteen inches long, and twenty and a half broad; the bill is dusky, triangular, and near two inches long; the crown of the head is crimson, spotted with black; the eyes are surrounded with black, beneath which the males have a crimson mark; the back, neck, and lesser coverts of the wings, are green; the rump of a pale yellow; the greater quill-feathers are dusky, spotted on each side with white; the tail consists of ten stiff feathers with black tips, and barred alternately with dusky and deep green; the whole hinder part of the body is of a very pale green; the thigh and vent are marked with dusky lines; the legs and feet all of a cinereous green.

The greater-spotted wood-pecker, *picus major* of Linnæus, called also *witwall*, weighs two ounces three-fourths, is nine inches long, and sixteen broad; the bill is one inch and a quarter long, of a black horn colour; the irides are red; the forehead is of a pale buff colour; the crown of the head of a glossy black; the hind part marked with a rich deep crimson spot; the cheeks white, bounded beneath by a black bar passing from the corner of the mouth, and surrounding the hind part of the head; the neck is encircled with a black colour; the throat and breast are of a yellowish-white; the vent-feathers of a light crimson; the back, rump,

and coverts of the tail, and lesser coverts of the wings, are black; the scapular feathers and coverts, adjoining to them, are white; the quill-feathers black, elegantly marked on each web with round white spots: the four middle feathers of the tail are black; the next tipt with yellow; the bottom of the two outmost black, the upper parts a dirty white; the exterior feather marked on each side with two black spots; the next with two on the inner web, and one on the other; the legs are of a lead colour. The female wants the crimson spot on the head. This species is much more uncommon than the preceding; and keeps altogether in the woods.

The middle wood-pecker, or *picus medius* of Linnæus, agrees with the preceding in size and colours, except that the crown of the head in this is of a rich crimson; the crown of the head in the male of the former being black, and the crimson in form of a bar on the hind part.

The lesser-spotted wood-pecker, *picus minor* of Linnæus, is also called *bickwall*, and has all the characters and actions of the greater kind, but is more rare. Pennant.

WOOD-Pigeon. See **RING-DOVE**.

WOOD-Plea Court, is a court held twice a year in the forest of Clun, in Shropshire, for determining all matters relating to wood, and the feeding of cattle there. Perhaps it was originally the same with wood-mote court.

WOOD-Pucerons, in *Natural History*, a name given by M. Reaumur to a small species of insect of the puceron kind, of a greyish colour, and distinguished by its two hollow horns on the hinder part of its body.

These animals very much resemble, both in shape and size, the pucerons of the alder; but as those live always on the surface of the stalk, these make their way deep into the wood of a tree.

M. Reaumur found large quantities of these lodged at a considerable depth in the wood of some elms, after they were cut down; the passages, by which they had made their way in, were not to be found; but they were lodged in large and long holes, of the diameter of a goose-quill, and running many inches along the tree in a longitudinal direction.

All the pucerons found in those places appear to be females, and none have wings; they all have vast numbers of young ones of different degrees of maturity within them, and these may be forced out with pressing their bodies. Reaum. *Hist. Insect.* vol. vi.

WOOD-Root, or *Wood-ruffe*, in *Botany*. See **ASPERULA**.

The leaves and roots dried have been esteemed aperient and diuretic; and recommended in obstructions of the liver, and thence supposed efficacious in the jaundice: but they are now disused.

WOOD-Sage. See **SAGE**.

WOOD-Soot, in *Agriculture*, a substance of the foot kind, which has been found highly beneficial as a manure in cases of cold clayey or stiff loamy soils or lands, when in either the state of pasture or in that of tillage for grain, or other arable crops.

It is stated to be used in these proportions on different sorts of land. On light loams, when for pasture, from twenty-two to twenty-four bushels on the acre; when for barley, from thirty-three to thirty-four; for turnips, from thirty-three to thirty-six.

On chalky loams, when for pasture, from twenty-three to twenty-six bushels on the acre; when for turnips, from thirty-three to thirty-eight; for barley, from thirty-five to forty.

On strong loams, when for pasture, from twenty-two to twenty-

twenty-six bushels on the acre; when for artificial grasses, or green crops, from twenty-eight to thirty-four. See *Soot* and *Wood-Soot*.

Wood-Sorrel, in *Botany*. See *Wood-SORREL*.

Wood-Spitz, in *Ornithology*, an English name given by many to the common green wood-pecker.

Wood-Wash, in *Agriculture*, a name sometimes applied to dyer's-broom by farmers.

Wood, Waxen, in *Gardening*. See *GENISTA*.

Wood, in *Geography*, a county of Virginia, with 3036 inhabitants.

Wood Creek. See *PRESTON'S Creek*.

Wood Creek, a river of New York, which runs into the Hudson, near Fort Edward.—Also, a river of New York, connected with the Mohawk by the canal at Rome, through which the navigation is extended into Oneida lake.—Also, a river of New York, which rises in Kingsbury, and runs N. by Port Anne village, into lake Champlain, at Whitehall landing, formerly Skeneborough.

Wood Island, a small island near the coast of Maine; 15 miles N.E. of Cape Porpoise. N. lat. $43^{\circ} 26'$. W. long. $70^{\circ} 24'$.

Wood River, a river of North America, which runs into the Mississippi, N. lat. 44° . W. long. $92^{\circ} 25'$.—Also, a river of North America, which runs into the Mississippi, N. lat. $38^{\circ} 25'$. W. long. $90^{\circ} 58'$.

WOODBERRY, a township of Pennsylvania, in the county of Huntingdon, with 1107 inhabitants.

WOODBIDGE, a large and populous market-town in the hundred of Loes, and county of Suffolk, England, is situated on the banks of the river Deben, at the distance of 8 miles E.N.E. from Ipswich, and 77 miles N.E. by E. from London. It is said to have taken its name from a wooden bridge built over a hollow way to make a communication between two parks, separated by the road which leads towards Ipswich; and near the spot where this bridge is supposed to have stood is a house, which to this day retains the name of the Dry Bridge. But when it is considered that in ancient times this town was written *Oddebruge*, or, as in *Domesday-book*, *Udebruge*, it may with greater probability be supposed thence to have derived its present appellation. The principal streets in Woodbridge, one of which is nearly a mile in length, contain many good houses, and are well paved. The market-place is well-built, and in the centre of it is an ancient shire-hall, where the quarter sessions for the liberty of St. Ethelred are held; under which is the place for the corn-market. A weekly market, granted in the reign of Henry III., is held on Wednesdays, and here are two annual fairs. The only manufactures are those of sack-cloth and salt: but the commerce is of great importance. The Deben, which towards its mouth is called Woodbridge-haven, is navigable up to the town, which thereby carries on a very considerable traffic in corn, flour, malt, and various other articles, with London, Hull, Newcastle, and the continent: here are several docks for building vessels, with commodious wharfs and quays. In the population return of the year 1811, Woodbridge is stated to contain 702 houses, occupied by 4332 persons. The church, a spacious structure, is considered to have been built in the reign of Edward III. by John, lord Seagrave. It consists of a nave, chancel, and two side aisles, the roofs of which are supported by fourteen beautiful slender pillars. The exterior walls are of black flints, as is also a large quadrangular tower, 108 feet in height; near the top, the flint and stone are curiously intermixed in various devices. On the south side of the church formerly stood a priory for black canons of the Augustine

order. At the dissolution the site was granted by Henry VIII. to John Wingfield. After passing through several families, the estate was divided and sold, when the capital mansion, called the abbey or priory, was purchased by Francis Brooke, esq. of Ufford. The town contains meeting-houses for Independents, Quakers, and Methodists; also a free grammar-school for ten boys, sons of the poorer inhabitants of the town, who are to be instructed in Latin and Greek, and fitted for the university. Here is likewise an alms-house, worthy of particular notice, which was founded and endowed in 1587, under a patent of queen Elizabeth, by Thomas Seckford, esq. for thirteen men and three women. The endowment was an estate in Clerkenwell, London, then let for 11*l.* 13*s.* 4*d.*; but leased in 1767 for sixty years at 563*l.* per annum, clear of all charges. And as vast sums have been recently expended upon the estate, it may reasonably be supposed that a considerable advance will take place at the expiration of the lease. The governors are the master of the rolls and the chief justice of the common pleas, who are empowered to make such regulations as from time to time shall be necessary. By the last ordinances, the annual allowance to the residents in the alms-house was increased to 27*l.* for the principal or nominal governor, and 20*l.* to each of the other twelve poor men, besides wearing apparel, and a chaldron and half of coals. The three women are appointed as nurses and attendants on the men, and receive 12*l.* per annum, and clothing. The men wear a silver badge, with the Seckford arms, and are required to attend divine service at the parish-church on Sundays, Wednesdays, and Fridays, and all holidays.—Kirby's *Suffolk Traveller*, 8vo. 1764. *Beauties of England and Wales*, vol. xiv. Suffolk, by F. Shoberl.

WOODBIDGE, a town of New Jersey; 4 miles N. of Amboy.

WOODBIDGE, a township of Connecticut, in the county of New Haven, with 2030 inhabitants; 7 miles N.W. of New Haven.

WOODBURY, a town of the state of Connecticut, in the county of Litchfield, with 1963 inhabitants; 30 miles S.W. of Hartford.—Also, a town of the state of New Jersey, on the E. side of the Delaware; 9 miles S. of Philadelphia. N. lat. $39^{\circ} 51'$. W. long. $75^{\circ} 15'$.—Also, a town of Vermont, in the county of Caledonia, with 254 inhabitants; 20 miles N. of New Haven.—Also, a township of Pennsylvania, in the county of Bedford, with 1658 inhabitants.

WOODCHESTER, a parochial village in the hundred of Longtree, and county of Gloucester, England, is situated $2\frac{1}{2}$ miles S.W. from Stroud, $12\frac{1}{2}$ S. from Gloucester, and 104 W. by N. from London. In 1811 the number of houses in the parish was 162, and the inhabitants 845. By its name Woodchester indicates its having been originally a Roman station, and many Roman antiquities have been frequently discovered there, of which the most remarkable is a mosaic pavement, partially laid open by digging graves in the church-yard under which it lies. It appeared to have formed a square of 48 feet 10 inches; and for size and richness of ornament is certainly superior to any similar tessellated pavement hitherto discovered in Britain. The tesserae were imbedded in a cement about 8 inches thick: and under all were flues crossing each other at right angles. Besides this curious work, others have been occasionally discovered at Woodchester: particularly in 1795 and 1796, the ground-plot of a very extensive Roman building was laid open, of which the remains in the church-yard formed the N. extremity, and the other parts extended under an adjoining orchard and field. The plan of this building comprised two courts,

courts, which, with the great room, containing the principal pavement, ran through the middle, having numerous apartments of different dimensions branching out from them. In three large rooms on the N. side of the great or first court were found fragments of columns, statues, and marbles. The second or inner court had galleries on three sides. The great mosaic pavement seemed to have belonged to the *cavaedium*, an interior court or hall, which communicated with several suites of rooms. Various parts of the building appear to have belonged to the apartments allotted for baths, exercise, &c. That these remains were portions of a splendid Roman villa is scarcely to be doubted; and from their character the villa may have been the residence of the pro-prætor, while Britain was subject to Rome. Fragments of statues, pottery, stags'-horns, glass, and coins, have been found among the ruins. Of the coins, the oldest was one of Hadrian, and the latest of Valens. A dagger of iron, much corroded, two spurs of the same metal, a small brass hatchet, a fibula, a key apparently of hardened clay, &c. were also discovered. The manor of Woodchester belongs to lord Ducie, who has a seat at Spring-park, in the parish, now deserted. It is romantically situated amidst fine woods. A full account of the Roman villa, with plates, has been published by S. Lysons, in imperial folio.

WOODCOCK, —, in *Biography*, one of the Hereford waits, with a strong hand on the violin, so famous in our youth for playing Vivaldi's Cuckoo concerto, that he was sent for far and near to perform it at country concerts. See **VIVALDI**.

WOODCUTTER'S CREEK, in *Geography*, a river of East Florida, which runs into the Atlantic, N. lat. $29^{\circ} 57'$. W. long. $81^{\circ} 40'$.

WOODEN, a town of Poland, in the palatinate of Lublin; 52 miles N. of Lublin.

WOODEN Ball, a small American island, near the coast of Maine. N. lat. $43^{\circ} 50'$. W. long. $68^{\circ} 40'$.

WOODEN Frames, for preserving and retarding the Blossoms of Fruit-trees, in *Gardening*, such as are contrived for the purpose of protecting the blossoms of them from the destructive effects of spring-frosts, &c. In this intention nets of different kinds, and screens of canvas rolled up in the day-time and let down at night, or in the time of heavy rains, have been mostly employed while the trees are in flower; but these frames are found to be superior, especially in exposed northern situations. By means of thus retarding and defending the blossoming of these sorts of tender trees, until the frosts be chiefly over, much advantage is said to be gained in the setting of the fruit.

These frames are constructed in a simple cheap manner; the revolving parts of which are covered with the branches of the silver fir, or those of some other such tree, which are found to answer the purpose very effectually; and when they are properly formed, they will open and shut with the greatest ease and expedition. They are in use from about the middle of February until towards the end of April, or later in some cases; being only opened as there may be a necessity in the state of the blossoms.

They have been employed with great success for peaches and apricots, and may be used for many other sorts of tender fruit-trees.

In forming them, the upright posts are made of wood, two inches square, and fourteen feet six inches long, into which cross-bars are mortised; the poles standing six feet asunder. The upper leaves, which open outward on their pivots, are made of inch-deal, by an inch and a quarter in breadth. There are small pieces of wood nailed on the insides of the upper and middle bars, to prevent the leaves of

the frames from falling inward on the wall. The lower leaves of the frames, which open out above, in order to admit the rays of the sun to the lower parts of the wall, revolve on pivots. The bottom or low end of the frames stand out two feet from the wall, and every other pole in them is fixed at the top, with an iron holdfast immediately under the coping of it. The leaves of the frames are covered with branches of the silver fir, so as to wholly occupy the vacant spaces at the end, middle, and sides of them. The cross-bars are made of inch and quarter wood, and of a breadth to correspond with the upright poles into which they are mortised. There are small wooden pins in the ends of the cross-bars, to hold the frames tight when they are up. The space between the wall and the frames should have a sort of partition at every twelve feet, formed by the silver fir-branches, tied to the trees and every second pole, which will prevent a too free circulation of air along the wall, and preserve a degree of serenity very essential to the setting of the fruit.

These frames may be found very beneficial in many open and exposed aspects of garden-grounds. See a paper on the subject in the first volume of the "Memoirs of the Caledonian Horticultural Society."

WOODEN Hoop for Cheese, in *Rural Economy*. See **DAIRYING**.

WOODEN Horse, in *Military Language*. See **HORSE, Wooden**.

WOODEN Horse-Collar. See **COLLAR**.

WOODEN Saddle. See **PACK-Saddle**.

WOODEN'S Island, in *Geography*, a rocky islet in the North Pacific ocean, on the S. coast of King George III.'s Archipelago: so called by captain Vancouver, from Isaac Wooden, one of his crew, who fell overboard near it, and was drowned, a little to the east of Cape Ommaney.

WOOD-ENGRAVING, or *Xylography*, is the art of making such incisions and hollows, imitative of natural or ideal objects, at the will of the designer, on a block or tablet of wood, as may afterward yield impressions on paper, its surface being supplied with printers'-ink in the manner of letter-types.

The wood of the apple or pear-tree, either of them occasionally, but more frequently the pear-tree, was used by those engravers of the European continent, who flourished during the 14th, 15th, and 16th centuries, and is believed to have been used for the same purpose, from a much earlier period, in China. The reason of this preference is the superior compactness of the texture of those woods: but the wood of the box-tree has latterly—for the same reason, namely, because it is yet more compact than the pear-tree in its grain, and harder in its substance—superfeded it; at least for the smaller purposes of such book-blocks as are intended to be combined in the letter-press, and printed at the same operation with alphabetic types.

The instruments used in this art are few and simple; and are probably the same now, with a few improvements of no great importance, that have been in use from the very commencement of the art: namely, *gravers*, more or less square or lozenge in their proportions, according to the breadth and depth of the lines required to be cut; *scrapers*, of various sizes, both flat and round, but chiefly the latter; *knife-tools* and *spit-slickers*, for the finer lines, pecks, or stipplings; and *gouges*, for the broader and deeper hollows, which are intended to be left untouched by the ink and paper in the process of printing.

The designs which formed the subjects of the more ancient engravers in wood, consisted either of pure outlines, or very little more than outlines; the engraved blocks or tablets

WOOD-ENGRAVING.

tablets furnishing merely the lineaments of the figures, &c. represented, and the colourist, or illuminist, (as he has sometimes been termed,) supplying the rest. By degrees a few light hatchings were introduced, thinly scattered upon the folds of the draperies, shadows of the flesh, and other parts of the design; and occasionally, when the opening of a door or a window, or the mouth of a cavern, was to be expressed, the block was left untouched, that it might print black in such places, and thereby diminish the task of the colourist. It was soon discovered, that with little additional labour of the wood-engraver, much more might be accomplished. It was easy to represent the bugbear figure of Lucifer with its appropriate blackness, and at the same time to express the internal markings of his body and limbs, by means of thin lines cut in the block, and which would be rendered white in the impression.

The ornamental borders which, in some instances, surrounded the devotional cuts of those times, were rendered more attractive to the eye, by the opposition of broadish white and black lines; and sometimes intermediate spaces of greater extent were enlivened by large white dots cut out, or perhaps punched at equal distances, on the block; or decorated with sprigs of foliage, or small flowers, relieved by a similar process, upon a black ground. Gradations of shadow next began to be attempted in the figures and other parts of wood-engravings, by means of white dots, differing from each other in their magnitude and proximity according to the degree of shade or darkness required.

This mode of finishing engravings in wood appears to have been practised at Mentz, among other places, at an early period of the invention of typography, and was afterwards occasionally resorted to by the wood-engravers of other countries; especially those of Paris, where, at the close of the 15th and commencement of the 16th centuries, numerous small books of devotion were printed by Antoine Verrard, Simon Vostre, and others, in which the borders surrounding the pages were decorated by figures very delicately engraved, and relieved upon a black ground, specked over, with extreme nicety of workmanship, with minute white dots, such as have been described.

These innovations or improvements in the art of wood-engraving, were such as involved but little additional labour or difficulty in the execution; at the same time, they were calculated to give to the decorations of books a shewy effect: but the artists of Germany, finding or fancying them to be incompatible with the purpose of imitating by wood-cuts the appearance of their original designs, the former and more simple method was again resorted to.

It appears to have been at the earlier period of the art the practice of those masters, who furnished designs for the wood-engravers to work from, carefully to avoid all cross-hatchings, which it is probable were by many persons considered as beyond the power of the xylographist to represent. Wolgemuth perceived that though it was difficult to effect cross-hatchings, it was not impossible; and in the cuts of the Nuremberg Chronicle,—the execution of which he doubtless superintended, beside furnishing the designs,—a successful attempt was first made to imitate the bold hatchings of a pen-drawing, crossing each other, as occasion prompted the designer, in various directions. To Wolgemuth belongs the praise of having been the first who duly appreciated the powers of this art; and it is more than probable that he proved with his own hand, to the artists who were employed under him, the practicability of the style of workmanship that he required.

Engraving on wood now offered inducements to its practice, which had not before been contemplated. Albert

Durer early applied himself to the study and further advancement of an art which at once promised to reward his labours with fame and fortune; and so well had Nature qualified him for the task, that before the termination of the 15th century, he produced his series of wood-cuts of the Apocalypse; a work which it cannot be doubted was received throughout Europe with wonder and universal applause.

Mr. Bartsch strongly insists that neither Durer, Schauflein, Burgmair, nor the other great designers of the German school, who were contemporaneous, or nearly so, ever engraved in wood themselves; but that all they did was to furnish the designs, leaving the task of cutting them upon the tablets to the ordinary engravers in wood. Mr. Ottley is, however, persuaded that this opinion is in a great measure erroneous, notwithstanding the inscriptions which Bartsch refers to, written anciently upon the backs of so many of the engraved tablets of the celebrated triumph of Maximilian, and other works designed by Hans Burgmair, and recording the names of the individual wood-engravers who were employed to execute particular pieces of those extensive undertakings.

One hundred and thirty-five of the folio tablets of Maximilian's triumph are still preserved in the imperial library at Vienna, where an edition of them was struck off in the year 1796. According to Bartsch, they were engraved from the design (for the whole forms but one long procession) not of Albert Durer, as had formerly been supposed, but of Hans Burgmair, in 1516 and the three following years. The names of the different wood-engravers employed are written, says Mr. Bartsch, upon the backs of several of the blocks, in the following manner. Upon N^o 18. of the edition just mentioned, "Der kert an die Ellend. hat Wilhelm geschitten;" *i. e.* this block joins to that which represents the elks. It was engraved by William: and so of the rest.

The names or initials of engravers found upon the backs of these extraordinary tablets are seventeen in number, and are as follow: 1. Jerome André, surnamed Resch, or Rösch (one of the most eminent engravers of Nuremberg.) 2. Jan de Bonn. 3. Cornelius, (perhaps Cornelius de Bonn.) 4. Hans Frank. 5. Saint German. 6. Wilhelm. 7. Corneille Liefrink. 8. Wilhelm Liefrink. 9. Alexis Lindt. 10. Joffe de Negker. 11. Vincent Pfarkecher. 12. Jaques Rupp. 13. Hans Schaufelien. 14. Jan Taberith. 15. F. P. 16. A monogram, composed of H. F. 17. W. R.

The imperial library likewise possesses an hundred and twenty-two blocks, engraved from the designs of Burgmair, representing the saints, male and female, of the family of Maximilian. One hundred and nineteen of these were republished in the year 1799; and upon the backs of the blocks were found the names of the eight following engravers on wood; *viz.* 1. Hans Frank. 2. Corneille Liefrink. 3. Alexis Lindt. 4. Joffe de Negker. 5. Wolfgang Resch. 6. Hans Taberith. 7. Wilhelm Taberith. And, 8. Nicholas Seeman. Probably no writer who has entered upon a critical examination of these early works has been so well qualified to judge of them as Mr. Ottley: and that gentleman, while he admits that these inscriptions of names sufficiently prove that the great bulk of the numerous wood-cuts bearing the initials of Burgmair, were not cut upon the wooden blocks by his own hand; and that by parity of reasoning it might be fair to conclude the same of a large proportion of those bearing the monograms or initials of Durer, and other eminent designers; yet he can by no means persuade himself that the abilities of the ordinary wood-engravers, who abounded in Germany at the

close of the 15th century, could have been such as to render them in any material degree instrumental in bringing about that sudden and considerable improvement which took place in their art at that period. They had been accustomed to manufacture the barbarous wood-cuts used by the illuminists and venders of playing-cards, and were probably incapable of comprehending or appreciating those delicate, but free and masterly touches, which characterize the designs of a great and finished artist like Durer; and if so, wholly unqualified to represent them with any tolerable degree of fidelity. We may, therefore, readily believe that the numerous and flourishing school of wood-engravers, which we find spreading over Germany, and from thence to Italy, in the early part of the 16th century, owes its excellence to the great designers of that time; and especially to Albert Durer, who during his youth assiduously applied himself to the practice and improvement of the art, and afterward taught it to numerous pupils, who, already grounded in the principles of design, and working continually under the eye of their master, by degrees became qualified to assist him greatly in his numerous works of this kind. The intelligence, the delicacy, and the feeling, which we observe in the execution of most of the wood-cuts of Albert Durer, can only, Mr. Ottley thinks, be accounted for in this way; and the reader will probably admit that his opinion on the subject is not a little strengthened by the circumstance of Durer having been himself the publisher of all his chief works of this kind, more especially when added to the fact, that of the years 1509, 1510, and 1511, during which so large a proportion of his wood-engravings were executed, we have scarcely any thing by his hand engraved in copper.

The sudden and considerable improvement of which we have spoken, consisted of a superior style of execution, as well as of design. The meagre and miserable forms derived from the legends of superstition, and the Greek painters of the dark ages, began to give way to a clearer view of nature; and the few and scanty single-lined hatchings, which rather indicated than expressed shadow, were superseded by those bold courses of lines, as if hatched with a pen, and crossed with second and in some instances with third courses of lines, which Wolgemuth introduced, and Durer improved.

This mode of execution appeared to many persons so very difficult, and requiring so much more of pains and patient labour than they were warranted by other parts of these engravings in believing to have been bestowed on them, as to have excited considerable doubts whether the prints which contain these dark crossings were really impressed from wooden blocks. They were by some persons rather supposed to have been printed from casts, for which the engraved blocks served perhaps as matrixes; and a controversy hinging on this doubt has been for some time carried on by antiquarian inquirers, with sufficient boldness on both sides. The truth, however, could only remain with one party, and the subsequent production by Mr. Ottley, of some of the engraved blocks of wood themselves, either from the hands of Albert Durer, or those of his disciples, has proved that the dark crossings were actually delivered from wood, and settled the controversy, as far as respects that artist and his contemporaries, if not his successors.

The readers of our account of the German school of engraving, may have observed that ourselves were among the number of sceptics. As the truth was our object, we willingly confess our earlier mistake now that the fact is ascertained; and have too much respect for truth and the public to feel the least backwardness in recording it. Whether we

flatter ourselves that we can afford this record out of the flock of our reputation, is for our private feelings. If from our expression of doubt, research in the right direction, and satisfactory ascertainment, have resulted, our scepticism has not been in vain; nor have we been in vain anxious to tell what we believed, as well as what we knew. Respecting the dark cross-hatchings which so frequently occur in the works of Albert Durer, Mr. Ottley's argument is conclusive: yet there are two things in his book on engraving, for which we cannot award to him the same approbation; and these are, his discontinuing his history precisely at the same epoch where Mr. Landseer had been obliged to break off a course of (published) lectures that are confessedly imperfect; and his mis-stating both the words and meaning of that writer, in the only place where he professes to have quoted him.

We shall next proceed to describe the modes of workmanship, or execution, which have prevailed among the more modern practitioners of the art; beginning with that which is in use for the more common or ordinary purposes, and following with those refinements of the art which are practised only by its superior professors. Our account will be followed by some anecdotes and remarks relative to the earlier history of the art, which we hope will prove in no small degree worthy of the notice of the connoisseur and print-collector.

Before the artist begins his engraving, the surface of the block or tablet which is to receive it, must, by means of an instrument termed a *scraper*, succeeding to a fine watch-spring saw, be made level, and sufficiently smooth for the reception of the design which is intended to be represented. Should this design be very simple in its nature, such as a small geometrical diagram, for example, being previously drawn on paper either with a black-lead pencil, or Indian ink, it is sometimes laid on an engraver's sand-bag, or other such hard cushion, and the block being carefully placed over it, a smart blow struck on the back of the block with a broad-faced hammer, will transfer the lines from the paper to the wood, in a manner sufficiently plain and accurate for such purposes, when by means of the gravers, gouges, scrapers, &c. which have been before mentioned, the engraver begins his work of incisions and hollows, scooping away the whole surface of the block, except the diagram, or other simple design required.

In other cases, the design to be engraven is either traced by passing a blunted steel-point over the outlines, the back of the drawing being rubbed with powdered red-chalk, or is sketched out with a black-lead pencil, and the different shades washed in with Indian ink, in the same manner as a chiaro-scuro drawing on paper. This method is used in making drawings for cuts to be introduced in common and cheap publications, in which a bold shewy effect is chiefly required. In engraving such drawings made on the wood, the artist renders the several forms and tints by incisions cut in the block; and the principle on which he proceeds may be readily conceived by recollecting (what we have alluded to in an earlier part of this article), that were the block to be printed before the engraver commenced his operations, it would yield merely a black spot: every incision therefore made in the block will produce the impression of a white line or hatching, and thus afford the means of introducing any portion of light that may be required. By the multiplication of these white lines or hatchings, the engraver lightens the tint at his pleasure; and by the various widths, thicknesses, crossings, and intertextures of the incisions thus made in the wood, not only the forms and various gradations of shadow from light to darkness, but also the textures or
external

WOOD-ENGRAVING.

external characters of the various objects which may enter into the composition, may be very well represented.

Another mode of proceeding is occasionally resorted to in cases where engravings of a superior and more elaborate character are required, and which we have reason to believe was first practised in England by our countryman, Mr. John Thurston. In these cases, all the light and curious part of the design are hatched in, line by line, by the draftsman or designer himself, on the block, and which is performed either with a pen and Indian ink, after the manner of those ancient artists of the German school of whom we have treated, or else with the more modern and elegant instrument, a black-lead pencil. In some instances we have known the whole composition in all its details, both of light and obscurity, thus finished upon the wood in the most elaborate manner, before the engraver began his work of incision and scooping; but in most instances, the shadows and parts requiring less definition, and where the engraver may with more safety be left to the guidance of his own judgment, are merely washed in with a camel's-hair pencil and Indian ink, as in the foregoing method. Or else the designer uses a black-lead pencil, with which he rubs or scumbles in the less important tints. And the drawing on the wood being thus prepared, the engraver proceeds with the manual and linear portion of it, by cutting away the interstices between the pencilled or penned lines, as in the ancient manner, and the washed portion is treated in the modern method which we have described above.

Considerable skill on the part of the engraver is sometimes requisite in finishing the work, in order to unite and harmonize the whole, in which the designer's aid is not unfrequently required, who on a proof impression taken for the purpose hatches and works, with a fine camel's-hair pencil and white paint, over the dissonant parts, regulating at the same time the general effect, the drawing of the parts, and the style of execution. This touched-proof, viewed in the reversing glass, is carefully copied by the engraver on his block, which concludes the process.

There is, however, in the nature of things, no reason whatever why these two characters of engraver and designer may not exist united in the same individual; nor are the instances of such union unfrequent in fact. Mr. Bewick, of Newcastle,—whose highly-enriched volumes of engravings of birds and quadrupeds, adorned with delightful vignettes, are master-pieces of the art, and have merited and found a place in almost every library,—possesses, with his xylographic powers, a fund of exquisite humour, an originality of thought, and an accuracy of observation of the details of nature; together with an adequate talent of expressing those observations, which are really as surprising as they are diverting and instructive.

We believe that this artist, or his deceased brother, was the first who adopted an expedient which the present writer has been informed was originally suggested by Mr. Bulmer, proprietor of the Shakspeare printing-office,—that of lowering a little the surface of his engraving, by means of a very broad flat scraper, in those parts where tenderness and delicacy of impression were more peculiarly desirable; a thing trivial in itself, yet of sufficient importance in works that have pretensions to be regarded as highly finished, to have been subsequently imitated by most of the other engravers in wood. Among those who in modern times have united in themselves the characters of designers and wood-engravers, should also be mentioned Mr. Clennell, who has executed some of his own energetic compositions in a vigorous and masterly style, which few have been able to surpass.

Mr. Thurston,—more versed in all the technic varieties of linear practicability, and more accomplished in his academic powers of delineating the human form through all its gradations of action, character, and expression, than any of his predecessors in the xylographic art,—in his habits of thought and style of design, is poetical, didactic, profound, allegoric, recondite, ideal. Of the professors of imitative art, who have wisely employed their talent to a moral purpose, few have improved and delighted us so much, or caused us to reflect so variously or so deeply. But though Mr. Thurston has engraved very successfully on copper, we believe that he has always entrusted his designs on wood to be executed by others, (some of them latterly by a son of promising talents,) and from the black-lead drawings of this artist, performed on the blocks themselves, have been produced the best engravings of the London and Liverpool schools. We subjoin the names and monograms of the principal of those artists who have been engaged in their execution:—T. Clennell, C. Nesbit , R. Branston , J. Thompson , H. F. P. Hole, W. Hughes.

By the two latter of these we have seen landscape subjects of recent execution, which have excited in us no small degree of admiration of their professional powers. In a park-scene after Cuijt, engraved by Mr. Hughes, (who professes to have studied under Mr. Hole,) the trees more especially,—which have been generally and justly regarded as objects more difficult to express in this mode of art, than almost any other species of objects whatever,—are treated with a degree of looseness, freedom, and local knowledge of the characters of their various foliage, and modes of branching and ramification, that we believe is quite unprecedented, and much more resembling an etching on copper from the needle of Waterloo or Middiman, than any former production of the wood-engravers' art. And there has also very lately appeared a book, entitled "The Club," after the designs of Thurston, which is not less excellent in its way. It consists of twenty-four characteristic head-pieces of the several members of the club, a title-page representing the club collectively, beside various tail-piece vignettes, and impresses us with a depth of philosophical penetration into the human character in all its varieties both natural and assumed; for here the nicer physiognomical traits which mark the lesser discriminations between wit, humour, and ridicule, in their various modifications, are faithfully rendered: indeed with a degree of delicacy and fidelity which until now we had not conceived to lie within this province of art.

In wood-engravings, like the best of these modern productions which we have mentioned, there is more original feeling, more of the truth of nature, and the blandishments of art, than in all the dry, monkish, legendary rubbish put together, toward which the dealers in and writers on such rarities (who are frequently the same persons) are so very anxious to attract and retain the public attention, and which are so ardently sought after by the wooden and would-be connoisseurs of the day.

Some few connoisseurs there are, nevertheless, that with great sensibility to the beauties of meritorious works of this kind, collect also the early rarities of the art as curiosities, and as interesting steps in tracing the march of European xylography, from its rude outset towards its present attainments: but the idle occupation which so many expensive books have ridiculously promoted, the affected exquisiteness of regard for what is merely scarce, and which, if it were plentiful, would be justly esteemed as mere rubbish, can scarcely be too severely reprehended, when we observe that

by giving an erroneous direction to the public taste, it operates as the very bane of modern merit, and of all principled encouragement of the art.

A man who collects these early rarities, and these only, may be pretty certainly pronounced to be a person of no intrinsic relish for the productions of art, and by no remote analogy may be easily perceived to be in the predicament of Rochefoucault's man of gravity, who assumes a mysterious carriage of the body to cover the defects of the mind.

Between the territories of Error and Truth, there is no neutral ground; neither can be made to recede without the other's advancing. Among the causes that, concurrently with the above, have retarded the progress of the art of wood-engraving, indifferent and bad printing ought first and chiefly to be mentioned; for this evil is feverely felt by all modern designers and engravers on wood, (and, like most other evils, by far the most heavily by the best,) the delicate parts of whose most elaborate performances are so frequently marred by this operation.

The bad printing of wood-cuts generally proceeds from one or more of the following mistakes, to use the mildest term that occurs to us: Printers being unable of themselves to judge of the effect required in an impression; their being generally too much restricted in price by the publishing-book-sellers to afford the necessary attention, even were they better informed; the false respect exacted by opulence, which renders them too ignorantly proud to submit to the direction of artists, who are generally poorer men than themselves; with which cause, prejudice in favour of old methods of practice is always ready to unite itself; the practice of over-damping English, French, and even India paper. To which may be added the use of blanketing, and the neglecting to have the engravings properly made ready under the direction of the artist: all of which lead to the general corollary, or inference, that the engraver should always superintend the printing of his own works.

WOOD-ENGRAVING, *Origin and Ancient History of.* Father Du Halde adduces very satisfactory reasons for our believing that the art of engraving on wood existed and was practised in China for several centuries before its appearance in Europe. Whether it is of Chinese transplantation, or spontaneous European growth; whether it was introduced by the Venetian traders and travellers to India, or was re-invented, as the baron Heinekin supposes, in Germany, by the Briefmalers and Formschnieders, who fabricated playing-cards, and the miserable legends of monkish superstition; or whether it was not discovered, as Papillon has asserted, at Ravenna, as early as the year 1285; have been examined with great critical attention, and at least as much perseverance as the public will sympathize with, by the abbé Zani, Mr. Otley, and others. To the works respectively of the Italian abbé, and the English historian and connoisseur, we refer those who may be desirous of obtaining more local and detailed information concerning the early curiosities of the art than belongs to the plan of our Cyclopædia. The story of the two Cunio, which they have repeated at great length from Papillon, and illustrated by their own more profound knowledge of the subject, is romantic in the extreme: so much so, that the antiquarian interest which the reader may feel with us on the score of the curious wooden blocks from "the life of the great and magnanimous Macedonian king," merges in the chivalry and fine art, the poetic and pictorial fervour, and the tragic fate, of the twin brother and sister, the ancient pride of Ravenna, and of the illustrious house of Cunio.

Papillon relates, that when he was a young man, he "discovered an epoch of engraving prints and characters on wood, certainly much more ancient than any hitherto known in Europe;" and the story of his discovery is, that being employed about a century ago in papering a closet for a Swiss captain of the name of De Greder, in the village of Bagneux, near Mont-Rouge, the captain, finding he possessed a taste for such matters, shewed him two or three very ancient volumes, and they conversed together concerning the prints contained in them, and the antiquity of engraving on wood. Papillon proceeds to give the description of the principal, *i. e.* the most ancient, of these volumes, as follows:—Upon a cartouch, or frontispiece, decorated with fanciful ornaments, and measuring about nine inches in width by six in height, with, at the top of it, the armorial bearings no doubt of the family of Cunio, are rudely engraven the following words, in bad Latin, or ancient Gothic Italian, with many abbreviations, which were rendered and explained to him by M. de Greder.

"The heroic actions represented in figures, of the great and magnanimous Macedonian king, the bold and valiant Alexander; dedicated, presented, and humbly offered to the most holy father pope Honorius IV., the glory and support of the Church, and to our illustrious and generous father and mother, by us, Alessandro Alberico Cunio, cavaliere, and Isabella Cunio, twin brother and sister: first reduced, imagined, and attempted to be executed in relief, with a small knife, on blocks of wood, made even and polished by this learned and dear sister, continued and finished by us together, at Ravenna, from the eight pictures of our invention, painted six times larger than here represented; engraved, explained by verses, and thus marked upon the paper to perpetuate the number of them, and to enable us to present them to our relations and friends, in testimony of gratitude, friendship, and affection. All this was done and finished by us when only sixteen years of age."

The cartouch mentioned above is enclosed in a square formed by a simple black line, one-twelfth of an inch in thickness; a few light hatchings, irregularly placed, and executed without precision, indicate the shadows of the ornaments. "Immediately following this frontispiece (says Papillon) are the eight pictures, engraved in wood, of the same dimensions, and surrounded by a similar fillet: they have also a few faint hatchings, to indicate the shadows. At the bottom of each of these prints, between the broad line or fillet which bounds the subject, and another parallel line distant from it about the breadth of a finger, are four Latin verses engraved upon the block, which poetically explain the subject; and above each is its title. The impressions of all of them are of a grey tint, and spotty; as if the paper had not been damped or wetted before it was laid upon the engraved blocks. The figures, which are passable in respect to their outlines, although of a semi-gothic taste, are sufficiently well characterized and draped; one may perceive by them that in Italy the arts of design were then beginning by degrees to experience melioration. The names of the principal personages represented are engraved under their figures, as Alexander, Philip, Darius, Campaspe, and others."

Papillon next describes the eight engravings severally, which bear the names respectively of the twins Alexander and Isabel Cunio, and it would appear from his descriptions that Isabel was the superior artist of the two.

Upon the blank leaf which follows the last print, badly written in old Swiss characters, and with ink so pale as to be scarcely legible, is the following memorandum.

"This precious book was given to my grandfather, Jan. Jacq. Turine, a native of Berne, by the illustrious count di Cunio, magistrate (podesta) of Imola, who hon-

WOOD-ENGRAVING.

noured him with his liberal friendship. Of all the books I possess, I esteem it the most, on account of the quarter from whence it came into our family; and on account of the science, the valour, the beauty of the amiable twins Cunio, and their noble and generous intention of thus gratifying their relatives and friends. Behold their singular and curious history in the manner in which it was several times related to me by my venerable father, and according to which I have caused it to be written more legibly than I myself could have done it." What follows is written in a better hand, and with blacker ink.

"The young and amiable Cunio, twin brother and sister, were the first children of the son of the count di Cunio, which he had by a noble and beautiful Veronese lady, allied to the family of pope Honorius IV., when he was only a cardinal. This young nobleman had espoused this young lady clandestinely, without the knowledge of the relations of either of them; who, when they discovered the affair by her pregnancy, caused the marriage to be annulled, and the priest who had married the two lovers to be banished. The noble lady, fearing equally the anger of her father and that of the count di Cunio, took refuge in the house of one of her aunts, where she was delivered of these twins. Nevertheless the count di Cunio, out of regard to his son, whom he obliged to espouse another noble lady, permitted him to bring up these children in his house, which was done with every instruction and tenderness possible, as well on the part of the count as on that of his son's wife, who conceived such an affection for Isabella Cunio, that she loved and cherished her as if she had been her own daughter; loving equally Alessandro Alberico Cunio her brother, who, like his sister, was full of talent, and of a most amiable disposition. Both of them made rapid advances in various sciences, profiting by the instruction of their masters; but especially Isabella, who, at thirteen years of age, was already considered as a prodigy; for she perfectly understood and wrote Latin, composed verses, had acquired a knowledge of geometry, was skilful in music, and played upon several instruments; moreover, she was practised in drawing, and painted with taste and delicacy. Her brother, urged on by emulation, endeavoured to equal her; often, however, acknowledging that he felt he could never attain to so high a degree of perfection. He himself was, nevertheless, one of the finest young men of Italy; he equalled his sister in beauty of person, and possessed great courage, elevation of soul, and an uncommon degree of facility in acquiring and perfecting himself in whatever he applied to. Both of them constituted the delight of their parents, and they loved each other so perfectly, that the pleasure or chagrin of the one or the other was divided between them. At fourteen years of age, this young gentleman could manage a horse, was practised in the use of arms, and in all exercises proper for a young man of quality; he also understood Latin, and had considerable skill in painting.

"His father having, in consequence of the troubles of Italy, taken up arms, was induced, by his repeated solicitations, to take him with him the same year, (*viz.* at the age of 14,) that under the eyes of his father he might make his first campaign. He was entrusted with the command of a squadron of twenty-five horse; with which, for his first essay, he attacked, routed, and put to flight, after a vigorous resistance, almost two hundred of the enemy; but his courage having carried him too far, he unexpectedly found himself surrounded by many of the fugitives; from whom, nevertheless, with a valour not to be equalled, he succeeded in disengaging himself, without sustaining any other injury than that of a wound in his left arm. His father, who had flown to his succour, found him returning with

one of the standards of the enemy, with which he had bound up his wound: he embraced him, full of delight at his glorious achievement, and at the same time, as his son's wound was not considerable, and as he was desirous to reward such great bravery upon the spot, he solemnly made him a knight, (*i. e.* a knight-banneret,) although he was already one by his birth; dubbing him in the same place where he had given such proofs of his extraordinary valour. The young man was so transported with joy at this honour conferred on him in the presence of the troops commanded by his father, (who, in consequence of the death of *his* father, which had recently happened, was now become the count di Cunio,) that, wounded as he was, he instantly demanded permission to go and see his mother, that he might inform her of the glory and of the honour which he had just acquired; which was granted by the count the more readily, as he was glad to have this opportunity of testifying to that noble and afflicted lady (who had always remained with her aunt a few miles from Ravenna) the love and esteem which he ever continued to entertain for her; of which he certainly would have given more solid proofs, by re-establishing their marriage, and publicly espousing her, had he not felt it his duty to cherish the wife his father had obliged him to marry, by whom he had several children.

"The young knight, therefore, immediately set out, escorted by the remains of his troop, out of which he had eight or ten men killed or wounded. With this equipage, and these attendants, who bore testimony to his valour wherever he passed, he arrived at the residence of his mother, with whom he staid two days; after which he repaired to Ravenna, to shew a similar mark of respect to the wife of his father, who was so charmed by his noble actions, as well as by his attentions towards her, that she herself led him by the hand to the apartment of the amiable Isabella, who, seeing him with his arm bound up, was at first alarmed. He remained a few days in that city; but impatient to return to his father, that he might have an opportunity of distinguishing himself by new exploits, he set off before his wound was yet healed. The count reprimanded him for not having sent back his troop, and for not remaining at Ravenna till he was cured, and would not permit him to serve again during the rest of the campaign: shortly after, when his arm was perfectly healed, he sent him home, saying to him pleasantly, that he did not choose to be outdone by him all the remaining time the troops would continue in action that year. It was soon after this that Isabella and he began to compose and execute the pictures of the actions of Alexander. He made a second campaign with his father, after which he again worked upon these pictures, conjointly with Isabella, who applied herself to reduce them, and to engrave them on blocks of wood. After they had finished and printed these pieces, and presented them to pope Honorius, and to their other relations and friends, the cavalier joined the army for the fourth time, accompanied by a young nobleman, one of his friends, called Pandulfo; who, enamoured of the lovely Isabella, was desirous to signalize himself, that he might become more worthy of her hand before he espoused her. But this last campaign was fatal to the cavalier Cunio: he fell, covered with wounds, by the side of his friend, who, whilst attempting to defend him, was also dangerously wounded. Isabella was so much affected by the death of her brother, which happened when he was not yet nineteen, that she determined never to marry: she languished and died, when she had scarcely completed her twentieth year. The death of this beautiful and learned young lady was followed by that of her lover, who had always hoped that his attentions and affections towards her would be rewarded by her consent at length to become his,

and

and also by that of her mother, who could not survive the loss of her beloved children. The count di Cunio, who had been deeply afflicted by the death of his son, could scarcely support that of his daughter. Even the countess di Cunio, who loved Isabella with great tenderness, fell ill of grief for her loss; and would have sunk under it, had she not been supported by the manly fortitude of the count. Happily the health of the countess was, by degrees, re-established. Some years afterwards, the generous count di Cunio gave this copy of the actions of Alexander, bound, as it now is, to my grandfather; and I have caused the leaves of paper to be inserted, upon which, by my orders, this history was written."

From the name of pope Honorius IV. being engraved on the frontispiece of these ancient prints, it is certain that this precious monument of the art of engraving on wood was executed between the years 1284 and 1286; because that pope governed the church only for the space of two years, ending in April 1287. The epoch, therefore, of this ancient specimen of engraving, is anterior to all the books printed in Europe that have been hitherto known. Papillon adds, that it is very probable that the copy of the work, which is recorded to have been presented to pope Honorius, may very possibly be preserved in the library of the Vatican.

The baron Heinnekin and our countryman Strutt distrust the truth of this story of the twins and their ancient work; but the latter has let escape that he read the original French with hasty inattention, and the former, after offering his objections, is compelled to add, "still there must be something true in Papillon's account; for, from my knowledge of his character, and his manner when I conversed with him, I am firmly persuaded that he did not invent that which he told me."

On the other hand, Zani confesses his entire belief of the account of Papillon, finding in it, as he states, "every mark of truth;" and Mr. Ottley conclusively adds, that "Papillon from his infancy had begun to collect materials for illustrating the history of his favourite art, of which, as is well known, he became a professor of some eminence, having been instructed in it by his father, who was also an engraver on wood. This practical experience combined with research could not but give him great advantages, and render him the less liable to be deceived in his decisions.

"His remarks, indeed, are those of a man well accustomed to examine ancient prints. The blocks, he says, appear to have been printed by means of the pressure or friction of the hand, with a light tint of Indigo in distemper; he describes the impressions to be granulous in some places, as if the paper had been applied to the engraved block without being first damped. Now, it is well known that many of the very early wood-prints were printed without any mixture of oil in the colours used for the purpose; and there is good reason also to believe that the paper was often applied in its dry state. The observations of Papillon are, therefore, not only evidence that he examined these prints with great attention, but that his eye was habituated to very nice discrimination, touching all those particulars which, perhaps, more than any others that could be named, are guides to enable us to judge of the antiquity of wood-engravings. And the probity of Papillon's character seems to preclude the idea that he had any intention to deceive."

The general corollaries resulting from these elaborate inquiries, which have been pursued to much greater length than we have chosen to follow, are, that the *origin of European wood-engraving* is unknown, (that is to say, that no person is acquainted with the precise facts of *who* first en-

graved on wood in this part of the world, or *when* it was done); and the reluctant acknowledgment that it cannot be shewn to be an European discovery at all.

Notwithstanding the detailed prolixity with which the chevalier Cunio's own account of his graphic enterprise is written, and though he states that himself and his sister invented the eight designs or pictures from which their tablets were engraven, he says nothing of the far more important fact, had it been so, of their having invented an art of multiplying those designs, so much more likely to have been announced by an ardent youth of sixteen, had there been the least foundation for such an announcement. No. He was too sincere: and he probably knew also that pope Honorius, and his noble relatives, were too well acquainted with similar processes employed by the Italian carvers, sealers, book-binders, and other artisans of Venice and Ravenna, (for the bindings of books were even then ornamented by means of heated iron stamps,) to have believed him, had he been less attentive to truth. He evidently regarded, and expected that his readers would regard, what he terms in one place engraving, and in another execution in relief with a small knife, as an expedient which might have been adopted by any other person in the existing state of that kind of knowledge, and which himself and sister practised—in all probability from the imperfect report of some inexperienced reporter, who might be their instructor in drawing.

At the period of which we are treating, Venice, as is well known, was the splendid emporium of exotic luxuries; and the reader will not hesitate to believe, that, with the facilities of Italian intercourse which then subsisted, much of the imported knowledge would travel at least to Ravenna, along with those foreign commodities and that commercial enterprise which were then spreading through Europe. The father and the uncle of Marco Polo, who had penetrated to Tartary and to China, returned from their nineteen years of travel in the East, in the same year in which the Cunio were born. Nothing, therefore, is more likely, under all the attendant circumstances, than that these travellers brought home the information necessary to the rude practice of the wood-engravers' art from *China*, which we are inclined to deem the parent country of wood-engraving, paper, and printing; and that it thus became known, though through what particular medium cannot now be traced, to the illustrious and romantic twins of Ravenna.

Should it be objected here, that Marco Polo has not noticed this art, in the account which he has left us of the marvels which he had witnessed in China; the answer is obvious. Marco did not himself travel thither until after the first return of his father and uncle, nor did his book appear until ten years after that of "the heroic actions of the great and magnanimous Macedonian king," when wood-engraving would seem to have been no marvel. Marco very wisely preferred instructing the public in matters with which they were not hitherto acquainted.

In corroboration of this account may be mentioned, that the manner in which the work of the Cunio is described to have been performed, is precisely that in which the Chinese have from time immemorial engraven on wood, and in which they still continue to practise that art, as may be seen by any person who may please to indulge himself in the curiosity of inspecting those engraved or carved tablets of wood which are preserved in the museum of the Honourable East India Company, in Leadenhall-street.

We have pursued this mixture of fact and probability thus far, because it appeared to us to contain the best evidence on the subject that is now obtainable; and because even this seems to render the uselessly-protracted and never-ending disputes, which have been so long kept up by certain interested

relled print-dealers and their prey, and their literary jackalls, about the superior pretensions of Italy or Germany to the discovery of this art; a mere recreation of idle credulity; a waiting of controversial ink and strength in strenuous idleness; an affair of spurious importance between "tweedle dum and tweedle dee."

If ridicule might find any other place in our Cyclopædia than under the letter R, we should here have recommended these rakers together of early German and Italian rubbish; these disciples of their rival pretensions; these admirers of the miserable virgins, and meagre faints and favours of those dark ages of art, which preceded the resurrection of the antique sculpture; these complimenting and catalogue-making worshippers of the pagods of tastelessness, who affect such an exquisite feeling for their wooden prodigies, to be consistent, and use their utmost diligence in seeking after the chips of the twins of Ravenna, or the still earlier chips of the wood-engravers of China, and to tell the tasteless and doting world of bibliographical cognoscenti, that these antique excisions are "graceful," or even more "elegant," than those which Cupid in shaving from his bow, in the celebrated picture by Corregio, in the collection of the most noble the marquis of Stafford.

In order to confer as much of factitious importance as might be found practicable on those relics of early European engraving and printing, for which these writers affect so great veneration; and to keep up the delusive idea that xylography and block-printing were *invented* here rather than *seen* elsewhere, the difference between change of form and change of colour in rendering impressions has been dwelt on with some emphasis: but nothing in the process of impressing stamps is of more frequent and ordinary occurrence, than for sufficient dirt to accumulate in an intaglio stamp that has lain by for any length of time, to produce a change of colour in the first impression yielded after such lapse of time. It must even have been a common, because obvious and efficient, mode of cleaning out the engraver's work. How frequently must this have occurred in sealing, for example. How frequently does it occur now: and here, without genius or meditation, is the link supplied at once in the chain of petty causes and effects, that has been so much magnified by the stupidity and tastelessness of modern dealers and collectors.

Of the impression of eight copies, mentioned by Papillon, of the life of Alexander, from the hands of the Cunio, it is not known that any remain; nor will this excite surprise, when we reflect that entire editions of some works that have been subsequently printed, have been swept from the face of day. The wood-engravings which succeeded these by the interesting twins of Ravenna, or were produced about the same period, appear to have been honestly thought of at the time; that is to say, thought of very little, because unworthy of being thought of much. From their non-importance, they have either all disappeared, or, from the same cause, not having been dated, the age of such of them as do remain, if any remain, is not known. The former of these is probably the chief reason of their disappearance; for who would think of seeking for the tops of ballads, or the dying speeches of criminals, or dirty playing-cards, which were printed even fifty years ago, or of preserving such things if accidentally found? and the early European wood-engravings of which we are treating, until Michael Wolgemuth arose, and introduced his better works of this kind into the Nuremberg Chronicle, were scarcely of more consequence than these lowest objects of the notice of the vulgar.

But though the prints have disappeared, a decree of the

senate of Venice remains to attest their former existence, and that "the art and mystery of making cards and printed figures had," in the year 1441, "fallen to total decay, and this in consequence of the great quantity of playing-cards and coloured figures printed, which are made out of Venice." The decree proceeds: "to which evil it is necessary to apply some remedy, in order that the said artists, who are a great many in family, may find encouragement rather than foreigners; let it be ordered and established," &c. &c.

This edict, as Mr. Ottley has well observed, speaks of "the art of making cards and printed figures in terms which would have been every way appropriate, had the edict had for its object the establishment of the oldest manufacture of Venice; and when coupled with other circumstances, especially the account of the two Cunio, furnishes a strong ground for the conjecture that engraving in wood had from a very early period been practised by the Venetians, who may easily be supposed to have learnt it in the course of their commerce with the Chinese."

The "printed figures," which are spoken of along with the playing-cards in the Venetian edict, were of the superstitious or devotional character to which we have already alluded, and which are described by Heinnekin as being soon afterward common in Germany and the Low Countries, when they were, — both the legendary wonders and the playing-cards, — designated by the same general term, and manufactured by the same hands; that is to say, cut in wood by the *Formschnieders*, and coloured afterward by the *Briefmalers*. And to this testimony of the German writer, the professor Fufeli adds, that "in the vulgar tongue of Zurich, and still more in that of the Roman Catholic cantons of Switzerland, *Helgen*, which is a corruption of *Heiligen*, meaning holy faints, is used to denote any historical print." The reason he gives for which is, "the first prints represented the figures of saints, or other devotional subjects, and were, on that account, termed *Helgen*; the term, in process of time, became generic, as others do, and is now used to denote prints of any kind, even those of profane subjects."

Of these superstitious excitements of the vulgar, the baron states, that he saw several which he believes to be of ancient date in the library of Wolfenbuttel. "These pieces," says he, "are of the same dimensions as our playing-cards: they measure three inches and a quarter in height, by two inches and a half in width." There are also in the same library, at the end of the book entitled "*Ars Moriendi*," five prints, in which are engraved divers figures of angels, devils, dying persons, faints, &c. similar to playing-cards, and of the same size, each figure being marked with a letter of the alphabet.

An engraved outline of a figure of this kind, of St. Bridget writing, with the Virgin and Child above, surrounded by a sort of cloud of Gothic scroll-work, and behind her a pilgrim's hat, wallet, and staff, Mr. Ottley has brought forward from the collection of earl Spencer. Perspective is grossly violated here, and it is of more than twice the dimensions of an ordinary playing-card; but this print, with another mentioned by M. Thierry as being in the library of the public Academy at Lyons, and which is said to be dated 1384, Mr. Ottley thinks may help to fill up the chasm between the work of the Cunio; and the larger print of St. Christopher crossing the water with the sacred Infant, which is dated 1423, is also in the collection of the same noble earl, and will be found mentioned in a more particular manner in the commencement of our account of the *GERMAN School of Engraving*.

WOODFORD, in *Geography*, a county of Kentucky, bordering on the Ohio, with 9171 inhabitants, of whom 3179 are slaves. Versailles is the chief town, containing 488 inhabitants, of whom 235 are slaves.—Also, a town of Vermont, east of Bennington, in the county of Bennington, with 254 inhabitants.

WOODGURRY, a town of Hindooftan, in Bednore; 35 miles N.E. of Simogu.

WOODIOUR, a town of Hindooftan, in Coimbetore; 10 miles N. of Darapuram.

WOODRIFF, a town of Tunis; 7 miles N.W. of Gabs.

WOODRUFF, SWEET, in *Agriculture*, a perennial plant, which is eat by different sorts of live-stock; and the aromatic flowers of which, when infused in water, excel in flavour, it is said, the finest teas.

WOODS, *Lake of the*, in *Geography*, a lake of North America, so called from the multiplicity of wood growing on its banks, such as oaks, pines, firs, &c. Its greatest length is about 70 miles, and greatest breadth forty. It contains but few islands, and those small. N. lat. 49°. W. long. 90°.

WOODS, a town of South Carolina; 32 miles W.N.W. of Georgetown.

WOODS'S Bay, a bay on the straits of Magellan; 15 miles W. of Cape Froward. S. lat. 53° 58'. W. long. 72° 55'.

WOODS'S Island, a small island near the north coast of Jamaica. N. lat. 18° 12'. W. long. 76° 8'.

WOODSAMADRUM, a town of Hindooftan, in Golconda; 12 miles S. of Damapetta.

WOODSBOROUGH, a post-town of Maryland; 75 miles N. of Washington.

WOODSIA, in *Botany*, owes its name to Mr. R. Brown, who dedicates this genus to the commemoration of Mr. Joseph Woods, F.L.S., an excellent British botanist. A valuable paper on the Roses of this country, about to appear in the Transactions of the Linnæan Society, will abundantly prove Mr. Woods' claims to such a distinction, even were it far less indiscriminately bestowed than usual.—Brown Tr. of Linn. Soc. v. 11. 170. Sm. Compend. Fl. Brit. ed. 2. 152. Pursh 660.—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices dorsales*.

Gen. Ch. *Frustrification* in roundish groups, on the back of the leaf. *Involucrum* cup-like, open, small, nearly flat, jagged, fringed with awl-shaped, incurved, jointed hairs. *Capsules* several, obovate, on short stalks, crowded, in the centre of the involucre, each bound by a vertical, jointed, elastic ring, and bursting irregularly at one side. *Seeds* numerous, kidney-shaped, granulated, extremely minute.

Eff. Ch. Groups of capsules scattered, roundish, each seated on a capillary-fringed involucre.

Obs. We gladly here adopt the term *group*, as technically synonymous with *SORUS*, (see that article,) instead of dot, spot, or line, which are liable to much exception.

1. *W. ilvensis*. Long-leaved Woodfia. Br. n. 1. Pursh n. 2. (*Acrostichum ilvense*; Linn. Sp. 1528. Fl. Dan. t. 391. *Polypodium ilvense*; Swartz Syn. Fil. 39. Willd. Sp. Pl. v. 5. 198. "Schkuhr Crypt. 16. t. 19." *Nephrodium lanosum*; Michaux Boreal.-Amer. v. 2. 270. *Lonchitis aspera ilvensis*; Dalech. Hist. 1221. f. 3.)—Fronn pinnate; leaflets lanceolate, deeply pinnatifid, with numerous, nearly uniform, oblong lobes. This appears to have been first discovered in the Mediterranean isle of Ilva, whence the specific name, which is very exceptionable, the same species being found on rocks in the north of Europe, as well as in North America, from Canada to Virginia. We have American specimens from Mr. Francis Boott,

agreeing exactly with Siberian ones in the Linnæan herbarium. We know not of this species having been detected in Britain. The fronds, five or six inches high, grow erect, in dense tufts. Their stalks, not quite half that height, are brown, bearing, like the mid-rib of each principal leaflet, many strap-shaped, taper-pointed, membranous scales. The frond itself is oblong, or lanceolate, composed of twelve or more pairs of oblong lanceolate leaflets, or pinnae, opposite or alternate, each about an inch long, numerous pinnatifid; their lower segments wavy, nearly equal and uniform; upper confluent: their upper surface is even, nearly smooth, of a fine green; lower covered with pale brown scales, and crowded hairy groups of capsules.

2. *W. hyperborea*. Round-leaved Woodfia. Brown n. 2. t. 11. Pursh n. 1. Sm. Compend. 158. (*Acrostichum hyperboreum*; Liljebblad in Stockh. Trans. for 1793. 201. t. 8. *A. alpinum*; Bolt. Fil. Brit. 76. t. 42. *Polypodium hyperboreum*; Swartz Syn. Fil. 39. Willd. Sp. Pl. v. 5. 195. Sm. Engl. Bot. t. 2023. *P. arvonicum*; Fl. Brit. 1115. *P. ilvense*; With. 774. *Filicula pumila*, *Lonchitidis Marantæ* species *Cambrobritannica*; Pluk. Phyt. t. 89. f. 5.)—Fronn pinnate; leaflets heart-shaped, rounded, pinnatifid, lobes rounded, waved, unequal.—Native of alpine rocks, chiefly in the northern parts of Europe. It occurs, though rarely, on the highest summits of the Welsh and Scottish mountains. A smaller plant than the preceding, often not above an inch high, though generally about three inches. The leaflets are shorter, and more rounded, as well as their lobes; of a thinner texture; much less deeply pinnatifid, except at their base, where the bottom pair of lobes are often so deeply separated, as to form two little leaflets, wavy, or obscurely lobed, and sometimes of unequal size. The main stalk is scaly; leaflets hairy on both sides.

We readily agree with Mr. Brown, that some intermediate varieties of each species render the specific characters of both considerably difficult. Yet there seems no reason to doubt their being distinct plants. Mr. Bauer's delineation of this fern, in the Linnæan Transactions, excellently engraved by Warner, is one of the finest illustrations of a natural production that can any where be seen.

WOODSTOCK, (New,) in *Geography*, a borough and market-town in the hundred of Wootton, and county of Oxford, England, is situated 8 miles N.N.W. from Oxford, and 62½ W.N.W. from London. It has a market on Tuesday, and fairs on the 5th of April, Tuesday in Whitsun-week, 2d of August, 2d of October, Tuesday after the 1st of November, and 17th of December. The town sends two representatives to parliament, the mayor being the returning officer. The corporation consists of a mayor, a high-steward, a recorder, town-clerk, four aldermen, and sixteen common-council men. In 1811, the houses in Woodstock were 235, and the inhabitants 1540. The south part of the present church is a fragment of an ancient chapel; but the northern face and the tower were erected in 1785. Adjoining to the church is a grammar-school, founded in 1585 by Mr. Cornwell, a native of the place; and near the southern entrance of the town is a range of alms-houses, erected in 1793 by the dukes of Marlborough, for six poor widows. The town-hall, a stone building, has under it the market-place, and was erected in 1766, from a design of sir William Chambers, at the expence of the late duke of Marlborough. The principal manufactures of the town are those of gloves and of polished steel. Various articles of this steel have been executed with great delicacy, and sold at high prices. This manufacture was introduced into Woodstock at the beginning of the last century; but it

it has much declined, on account of the cheapness of the cutlery goods furnished by Birmingham and Sheffield. The glove-manufacture is of later date; but has increased in the present day so much, that from 300 to 400 pairs of gloves are made weekly in the town and the neighbouring villages, and thus afford employment for about 1400 women and girls, and 70 men. Old Woodstock, of which only one mansion and a few irregular houses remain, stood in a sheltered situation on the little river Glyme, which supplies the magnificent piece of water in Blenheim-park. The manor-house, or royal palace, on the N. bank of the deep valley of the Glyme, within the bounds of the park, was the residence of Fair Rosamond, whose romantic adventures are deeply interwoven with the history of Henry II.; but the building has long disappeared. In this palace, that king, in 1164, received the homage of Malcolm, king of Scotland, and Rice, prince of Wales. In 1275 Edward I. held a parliament at Woodstock, and there was born his second son, Edmund, as was also the renowned Black Prince. Woodstock was inhabited occasionally by Richard II., and there Henry III. narrowly escaped assassination by a fanatic priest: an attempt was there also made by Morisco on the life of Henry VIII. The old palace was afterwards employed as a prison for Elizabeth, his daughter. In the time of the civil wars it suffered severely from the parliament's party; and about a century ago the gate-house, the last fragment of the edifice, was pulled down. But Woodstock is most worthy of note for having produced Chaucer, who was born there about 1328. The house in which he afterwards resided, while the court was in the palace, stood at the W. end of the town, near the usual entrance into Blenheim-park. Some relics of this building are still pointed out.

The great object of attraction at Woodstock is the magnificent palace of Blenheim, with the surrounding grounds, water, and park. The honour and estates of Woodstock, long belonging to the crown, were in 1705 conveyed by queen Anne, on the address of the house of commons, to the illustrious John, duke of Marlborough, to preserve the memory of his eminent services as a warrior and a statesman; particularly for the signal victory obtained by him, and prince Eugene of Savoy, at Blenheim, in Germany, over the French and Bavarians, on the 2d of August 1704. The house was erected by sir John Vanbrugh, at a convenient distance from the S. brink of a deep dell, in which ran the Glyme. The general distribution of this superb structure consists of a central mass of building, inclosing two small courts, and connected by colonnaded wings to two spacious quadrangles, forming the grand court of entrance. The centre is ornamented with a Corinthian portico, surmounted by a pediment and military emblems. The wings are crowned with towers serving at once to contain the chimneys, and to contribute to the picturesque grandeur of the edifice. The garden-front, extending from E. to W. 348 feet, is grand and magnificent. The interior of the mansion contains many noble apartments, adorned with paintings of eminent masters; particularly with a series of mythological pictures from the admirable pencil of Titian, presented to the first duke of Marlborough by the king of Sardinia, and with portraits of many eminent characters by the best artists. The library, occupying the whole of the W. front, 183 feet long and nearly 32 wide, is a magnificent room, originally destined to be a picture-gallery, but afterwards furnished with the grand Sunderland collection of books, containing upwards of 17,000 volumes. At one end is a marble statue of queen Anne by Rysbrack. In the W. wing is the chapel appropriately fitted up, and containing a monument, by the same sculptor, of the first duke, his

duchess, and their two sons, who died young. In the E. quadrangle of offices is the theatre, originally a green-house, calculated to accommodate 200 spectators. Near the E. angle of the mansion an observatory was erected by the late duke of Marlborough, and provided with a complete apparatus for astronomical observations by Ramsden; a grand telescope by Herschel was presented to the duke by his majesty, after his visit to Blenheim in 1786. The state-approach to the palace is by a straight avenue from the N. extremity of the park, over the river, by a bridge of one spacious and two smaller arches. Flowing in a deep dell, the small stream is made to assume the appearance of a naturally-winding river, expanding below the bridge into a broad irregular lake; thus, with the bridge, according with the grandeur of the palace and the noble extent of the park. A lofty column is erected in the midst of the great avenue, surmounted by a statue of the great duke, and charged on the pedestal with inscriptions stating his services and rewards. In the N.W. part of the park of Blenheim, vestiges may be traced of the ancient road, Akeman-street. Nearly two miles W. from the park is the village of Stonefield, at which place was discovered, in 1711, a tessellated pavement 35 feet by 20, representing, among other figures, a Bacchus, with his thyrsus and cup, mounted on a tyger. In addition to this curious antique, in 1779 were discovered, near the same spot, the areas of a number of other apartments paved in the same manner; and adjoining were the remains of a bath with its hypocaust: Roman coins from Vespasian downwards were found on the same spot. A plan and some account of these remains have been published by Henry Hakewill, esq. architect.—*Beauties of England and Wales, Oxfordshire*, by J. N. Brewer, 8vo. 1811. The *Blenheim Guide*, by Dr. Mason, 12mo. 1817. *Havell's Views of Seats* include two fine Engravings of Blenheim Palace, and a critical Account of the House, Scenery, &c. folio, 1818.

WOODSTOCK, a town of the state of Connecticut, in the county of Windham, with 2654 inhabitants; 57 miles S.W. of Boston.—Also, a town of North Carolina, on the left bank of Pamlico river; 22 miles N.N.E. of Newbern.—Also, a post-town of Virginia; 112 miles W. of Washington.—Also, a post-town of Vermont, in the county of Windsor, with 2672 inhabitants; 5 miles N.W. of Windsor.—Also, a township of New York; 46 miles S. of Albany.—Also, a post-town of New Jersey; 26 miles S.S.W. of Philadelphia.

WOODVILLE, WILLIAM, M.D. in *Biography*, was born at Cockermonth, in the year 1752. Having received a good classical education in his native town, he was placed with a respectable apothecary, to whom he served a short apprenticeship. He afterwards proceeded to Edinburgh, where, after the usual residence, he obtained, in 1775, the degree of M.D., having written and defended a very ingenious thesis "De irritabilitate fibrarum motricium." After passing some time on the continent, he returned and settled near his native place, where he practised his profession five or six years. Dr. Woodville then came to London, and was soon appointed one of the physicians to the Middlesex Dispensary, the duties of which office he discharged in an exemplary manner. In 1790 he published the first part, which was afterwards completed in four quarto volumes, of a highly valuable work, intitled "Medical Botany." In 1791 he was elected physician to the Smallpox Hospital, in the room of the late Dr. Archer; and it may truly be said, that no man ever devoted, more conscientiously or zealously, time and great talents, to the promotion of an object, than did Dr. Woodville to improvement in the medical treatment of the patients, as well as in

the general government of the establishment. To the officers of the hospital, and those governors who took most interest in its welfare, his merits were well known; and some of the fruits of his genius and industry are before the public in a volume which was published in 1796, intitled "The History of the Small-pox in Great Britain, &c." This work, which it was the author's design to occupy two volumes in 8vo., was well conceived, including a brief history of the disease, and a review of all the publications on the subject of inoculation, with an experimental inquiry into the relative advantages of the various measures that had been recommended. Only the first volume of this work, which is well written, and contains much valuable information, was published, the happy discovery of the efficacy of vaccination having, in the author's opinion, superseded the necessity of the second appearing. Dr. Jenner's grand discovery made a due impression on the mind of Woodville; and as no other man had equal opportunities of witnessing and lamenting the ravages of the small-pox, so no person could be more sincerely anxious and active in the adoption of those means that were found adequate to guard mankind against that pestilence. It is very true, that on the subject of vaccination he was, like every body else, at first sceptical; but he suffered no opportunity to be lost of ascertaining its efficacy, and then of proclaiming his belief in it. Unhappily, in some of his early experiments an error was committed; he was not aware of the influence of the variolous atmosphere of the hospital. The result was, that in certain instances, either pure small-pox matter, or a deteriorated vaccine lymph, had been inserted into the arms of some patients. The effects were faithfully detailed; but being so different from those that had been described by Dr. Jenner, that excellent man and benefactor to the human race visited Dr. Woodville, with whom he argued and remonstrated on the subject. It is to be regretted that some asperities of remark took place between them, although both were equally and honourably engaged in the development of truth. The discussion, however, as is always the case, proved very useful in the dissemination of the new practice; and if Dr. Jenner had reason to find fault with the result of Dr. Woodville's early proceedings, he must have been abundantly gratified by his subsequent experiments and publications. The ample field in which Woodville was placed enabled him to vaccinate great multitudes, some thousands of whom he afterwards tested by variolous inoculation, and thus gave that publicity to vaccination, and that confidence in it, which it could not otherwise have attained in the course of many years. He was also ardently engaged in the inquiry into the nature and origin of the vaccine lymph; and, at his request, the writer of this short article three times inoculated him with fresh grease from the heel of a diseased horse. If in the heat and bitterness of contention men seek an apology for unguarded expressions and assertions, this cannot be granted to those who calumniate the dead; and therefore the statement in a late history of vaccination of Dr. Woodville having fallen a victim to the drinking of ardent spirits, is deserving of reprobation. Dr. Woodville cultivated the society of his professional brethren, by whom, on account of his talents and companionable qualities, he was held in high estimation; and one of those who enjoyed the intimacy of his friendship, from the period of his settling in London until the day of his death, contradicts the above unfounded calumny. His disease, which terminated in dropsy, had made such gradual advances during the last year of his life, that he frequently talked of his death, which no man ever contemplated with greater equanimity, as likely to take place about a certain assigned period.

He died at the hospital on the 26th of March 1805; and

on the 3d of April, a warm and just eulogium was pronounced over the body in the saloon by his friend Mr. Highmore. His parents having been Quakers, he by his own desire was interred in the Friends' burial-ground in Bunhill-fields, after a very appropriate address at the grave by Mrs. Pryor.

The editor is indebted for the preceding article to his much-esteemed friend J. Norris, etq., no less distinguished by his mental and moral qualities than by judgment and extent of reputation in his profession.

WOODVILLE, in *Geography*, a post-town of Virginia; 94 miles W. of Washington.

WOODWARD, JOHN, in *Biography*, was born in Derbyshire in 1664, and, being intended for trade, was apprenticed in London; but in a little while abandoned the shop for the sake of scientific pursuits. In 1687 Dr. Barwick took him into his family, and for the space of four years gave him instruction in medicine and anatomy. He then recommended him to the medical professorship in Gresham college, to which he was elected in 1692. Having directed his particular attention to fossils, with a view to which he had travelled through many districts of England, he published in 1695 "An Essay towards a Natural History of the Earth and terrestrial Bodies, especially Minerals; as also of the Sea, Rivers, and Springs; with an Account of the Universal Deluge, and of the Effects that it had upon the Earth," 8vo. His preparatory knowledge for a work of this kind was very slight, and therefore the execution of it was attacked by Dr. Martin Lister, and others. However, in the imperfect state of geology at that time, his performance engaged notice, and he was chosen in 1693 a fellow of the Royal Society. At this time he was in possession of an ancient iron shield, in the concavity of which was a sculpture representing the story of Camillus and the Gauls at Rome; and as it was a great curiosity among the learned, Dodwell gave an account of it in a Latin treatise, entitled "De Parma equestri Woodwardiana Differtatio." By this circumstance Woodward was led to increase his acquaintance with a certain class of literati, though he did not escape the ridicule of the wits. In 1695 he was created M.D. by archbishop Tenison, and in 1696 he obtained the same degree from Cambridge; and thus honoured, he was prepared for an admission into the College of Physicians as a fellow in 1702. But pursuing his inquiries into natural history and antiquities, he published some pieces in these departments: *viz.* "Some Thoughts and Experiments concerning Vegetation," communicated to the Royal Society, and printed in the Philosophical Transactions for 1669; "Naturalis Historia Telluris illustrata et aucta: accedit Methodica Fossilium in Classes Distributio," 1714, intended as a grand reply to those who objected to his Natural History of the Earth, which had been translated into Latin by Scheuchzer at Zurich; and "An Account of some Roman Urns, and other Antiquities, lately digged up near Bishopsgate; with brief Reflections upon the ancient and present State of London: in a Letter to Sir Christopher Wren." In his medical capacity, he published in 1718 "The State of Physic and of Diseases, &c." 8vo., in which he advanced the notion, that the bile and its salts, re-absorbed into the blood, were the true cause of life and animal motions, and that the same fermenting in the stomach were the cause of diseases; whence he was led to conclude that emetics to evacuate the morbid bile, and oily and unguinous medicines to correct it, were universal remedies. This publication produced a controversy with Dr. Freind, in which Woodward was answered both ludicrously and seriously, so that he gained little credit by his medical theory or practice. His chagrin, however, was diverted by the study of fossils, and the augmentation of his cabinet of specimens.

specimens. He soon after fell into a decline, which terminated his life in his apartments at Gresham college in 1727, at the age of 63. He bequeathed his personal property to the university of Cambridge, for the endowment of an annual lectureship, on a subject taken from his own writings in natural history or physic. Soon after his death were published an English edition of his "Method of Fossils," with various additions; and "A Catalogue of Fossils in the Collection of J. Woodward, M.D.," in 2 tomes, 8vo., a work of permanent estimation among geologists. In 1737 Dr. Templeman published Woodward's "Select Cases and Consultations in Physic," in which some valuable observations are interspersed. One of his hypotheses was, that the life resides in the blood, and in the separate parts of the body, not in the nerves; in confirmation of which he made many experiments, establishing the *vis insita* of muscles. Biog. Brit. Haller. Gen. Biog.

WOODWARD, an officer of the forest, whose function it is to look after the woods, and observe any offences either in vert, or venison, committed within his charge; and to prevent the same; and in case any deer are found killed, or hurt, to inform the verderor thereof, and present the delinquents at the next court of the forest.

Woodwards may not walk with bows and shafts, but with forest-bills. *Arcum et calamos gestare in foresta non licet, sed (ut rescripti utar verbo) hactenus tantummodo.* Term. Hil. an. 13 Ed. III.

WOODWARDIA, in *Botany*, a very fine and well-marked genus of ferns, dedicated by the writer of this article to the honour of his long and highly-valued friend, and botanical companion, Thomas Jenkinson Woodward, esq., LL.B., F.L.S., one of the best English botanists, whose skill and accuracy are only equalled by his liberality and zeal in the service of science. Mr. Woodward's name is well known as the important assistant of Dr. Withering in his national *Flora* (see WITHERINGIA), as well as by his communications to the Linnaean Society; amongst which, an essay on the *British Fuci*, written in conjunction with the present learned bishop of Carlisle, and printed in the third volume of that Society's Transactions, stands conspicuous.—Sm. Mem. de l'Acad. de Turin, v. 5. 411. t. 9. f. 3. Traçts 238. t. 1. f. 3. Willd. Sp. Pl. v. 5. 416. Swartz Syn. Fil. 116. Sprengel Crypt. Engl. ed. 131. t. 4. f. 29. Ait. Hort. Kew. v. 5. 523. Pursh 669.—Class and order, *Cryptogonia Filices*; sect. *annulatae*. Nat. Ord. *Filices dorsiferae*.

Eff. Cl. Groups of capsules oblong, distinct, straight, ranged in a simple row, in bordered cavities, parallel to each side of the rib. Involucrum superficial, vaulted, separating towards the rib.

Obs. Mr. Brown has separated from this genus, by the name of *Doodia*, Prodr. Nov. Holl. v. 1. 151, such species as have a flat *involucrum*, unconnected at its inner margin, and originating from an interbranching, or connecting, vein, at its opposite side. In these the *capsules* are not sunk into any bordered cavity, nor are the *groups*, with their *involucra*, so turgid, or prominent. *Woodwardia caudata*, Cavan. Leccion. 264. Swartz Syn. Fil. n. 2. Willd. n. 2, belongs to this genus of *Doodia*; and Mr. Brown defines two others, *aspera* and *media*, as likewise natives of New Holland, in which country, it seems, no true *Woodwardia* has been found.

1. *W. angustifolia*. Narrow-leaved Woodwardia. Sm. n. 1. Swartz n. 1. ("W. floridana; Schkuhr Crypt. 103. t. 111.") *W. onocleoides*; Willd. n. 1. Pursh n. 1. *Onoclea nodulosa*; Michaux Boreal.-Amer. v. 2. 272. Swartz Syn. Fil. 111. *Acrostichum areolatum*; Linn.

Sp. 1526. A. n. 12; Linn. Am. Acad. 274. *Osmunda caroliniana*; Walt. Carol. 257. *Lonchitis major virginiana*, folio vario, alis Polypodii in modum conjunctis; Morif. sect. 14. t. 2. f. 24. *Filix floridana*, prælongis et angustis pinnulis, &c.; Pluk. Amalth. t. 399. f. 1.)—Frons pinnate; leaflets linear, acute, entire; the barren ones finely serrated.—In cedar and cypress swamps, from New Jersey to Florida, fructifying in August. Perennial, about a foot high. *Pursh*. The root is creeping, scaly and shaggy, bearing several stalked, upright, smooth fronds, of a lanceolate figure, with a long taper point: the barren ones consisting entirely of lanceolate, acute, finely serrated leaflets, decurrent at their base, and somewhat confluent: the fertile of rather fewer, more distant, longer and narrower ones, likewise slightly decurrent and confluent at their base, each leaflet being nearly covered at the back, on each side of the rib, with a close series of turgid, nearly cylindrical, groups, a quarter of an inch long, of numerous capsules, every group closely covered by its own convex *involucrum*. Each group is encompassed with a considerably elevated uninterrupted line, bordering the hollow in which it lies. Willdenow has most unadvisedly changed the established specific name, without any right or pretence, surely for the worse rather than the better.

2. *W. japonica*. Blunt-lobed Japan Woodwardia. Sm. n. 2. Swartz n. 3. Willd. n. 3. Sprengel as above, f. 29. (*Blechnum japonicum*; Thunb. Jap. 333. t. 35. Linn. Suppl. 445.)—Frons pinnate; leaflets sessile, half pinnatifid, with close, obtuse, serrated lobes. Rows of fructification extremely close and crowded.—Gathered by Thunberg near Nagasaki, and in other parts of Japan, fructifying in June. Frond two feet, or more, in height. Stalk roughish, and somewhat scaly, not smooth. Leaflets five or six inches long, pointed, quite sessile, scaly at the base, each divided about half way to its rib into twelve pair, or more, of broad, bluntish, rounded, serrated lobes, above an inch long, and half an inch broad, quite close and parallel at the sides; paler beneath. Groups oblong, three or four in a continued line, close to the rib on each side. The *involucrum* reflexed to one side, after the capsules are fallen, leaves the cavity exposed, and like a box with its lid. The capsules appear all to be inserted into that margin of the cavity to which the *involucrum*, or lid, is attached.

3. *W. orientalis*. Sharp-lobed Japan Woodwardia. Swartz n. 4. also p. 315. Willd. n. 4. ("Blechnum radicans; Houtt. N. Hist. v. 2. t. 97. f. 1.")—Frons pinnate; leaflets stalked, deeply pinnatifid, with spreading, acute, serrated lobes. Rows of fructification close. Involucrum somewhat crescent-shaped.—Gathered by Thunberg in Japan. Very distinct from the last, as well as from *W. radicans*. The frond is more coriaceous than either, and seems to be rather glaucous. Stalk smooth and naked, at least in its upper part. Leaflets the size of the last, but tapering at their base into a short stalk; their segments considerably distant from each other, except at the very base, and somewhat revolute; sharply serrated, particularly at the point. Groups slightly lunate outwards, especially the upper and shorter ones, about seven in each row, crowded, and close to the rib. Perhaps it was from a specimen of this, confounded with the preceding, that Professor Thunberg described the main stalk as altogether smooth, and zigzag.

4. *W. virginica*. Virginian Woodwardia. Sm. n. 3. Swartz n. 7. Willd. n. 6. Ait. n. 2. Pursh n. 2. (*W. Banisteriana*; Michaux Boreal.-Amer. v. 2. 263. Swartz n. 8. *Blechnum virginicum*; Linn. Mant. 307. *Filix mas*, vulgari similis, pinnulis amplioribus planis, nec crenatis,

crenatis, virginiana; Pluk. Almag. 151. Phyt. t. 179. f. 2.)—Fronde pinnate; leaflets sessile, deeply pinnatifid, with spreading, obtuse, slightly crenate lobes. Rows of fructification accompanying their mid-rib as well as the ribs of the lobes.—In the swamps and shady woods of Virginia and Carolina. *Pursh*. We received it from Kew garden in 1785. The fructification is perfected in July and August. The frond is eighteen inches, or more, in height, with a pale smooth stalk. Leaflets alternate, above a finger's length, and about an inch, or more, in width, bright green, smooth; their numerous segments spreading moderately from each other, forming an acute angle at the base; their margin is somewhat revolute, and very obscurely crenate. Fructification most abundant on the leaflets of the upper half of the frond, forming lines all along their principal rib, at each side, as well as along the rib of each segment; the groups finally confluent. The depressions in which the groups are seated are very slight, though not imperceptible, and the involucre of each is narrower, less vaulted, and sooner turned aside, than in any other species with which we are acquainted, so that the present plant is in some measure intermediate between *Woodwardia* and *Doodia*. Perhaps it may prove these two genera not to be distinct, but while they remain so, we concur with Mr. Brown in keeping this species where it is. Plukenet's figure was drawn by Mr. Banister, the original discoverer of this fern.

5. *W. thelypteroides*. Small Woodwardia. *Pursh* n. 3.—“Fronde pinnate; leaflets sessile, linear-lanceolate, pinnatifid; villous at the base: segments of the barren ones oblong and bluntish; of the fertile ones shortened, triangular, and acute; all entire. Stalk downy, angular.”—In sandy swamps of South Carolina, near Charlestown, fructifying in July. Resembles the preceding, but is not half the size. *Pursh*.

6. *W. fimbriata*. Fringed Woodwardia.—Fronde pinnate; leaflets sessile, deeply pinnatifid, with spreading, rather acute, lobes, fringed with sharp teeth.—Gathered by Mr. Menzies, on the west coast of North America. This is larger in every part than *W. virginica*, and distinguished from that species by its more acute segments, whose margin is very conspicuously and copiously fringed with prickly teeth, directed towards the point. Groups of capsules large and turgid, ranged, a little obliquely, along the ribs of the segments, from three to five pair on each segment, none at the mid-rib of the leaflet itself. Involucre strongly and permanently vaulted. The bottom lobe of each leaflet, at the lower side, is shortened, dilated, and half heart-shaped, as is more rarely the case in *W. virginica*. Several of the upper leaflets are decurrent and confluent; the top ones undivided, and barren.

7. *W. radicans*. Rooting-stalked Woodwardia. Sm. n. 4. Swartz n. 5. Willd. n. 5. Ait. n. 1. “Schkuhr Crypt. 104. t. 112.” (Blechnum radicans; Linn. Mant. 307, excluding the reference to Plukenet, see *W. virginica*. Filix italica non ramosa maxima glabra, polypodii folio, gallas ferens, D. Micheli; Till. Pfl. 62. t. 24.)

β. *W. flans*. Swartz n. 6. “Schkuhr Crypt. 104. t. 113.” Willd.—Fronde pinnate; leaflets nearly sessile, deeply pinnatifid, with parallel, taper-pointed, sharply serrated lobes.—Native of deep clayey fissures of rocks in Madeira, according to Koenig. Found also in Italy and Portugal. A hardy greenhouse plant in England, and one of the most handsome of its tribe. The fronds are two or three feet high, and a foot and a half or near two feet in breadth, of a fine green, smooth, beautifully reticulated with veins, each main stalk producing at the back, near the top, a round scaly bud, or bulb, the origin of a young

plant. Leaflets generally alternate, often a span long, somewhat pectinate, with a long very slender point; their numerous segments more or less crowded, slightly curved, lanceolate, minutely and sharply serrated, each tapering to a sharp elongated point. Groups of capsules about seven pair on each segment, (none at the mid-rib of the leaflet,) close, direct, scarcely ever at all divaricated, turgid, pale brown, the cavities in which they lie very neatly and conspicuously bordered: uppermost leaflets simple and confluent, as in the foregoing species. We know not how the *W. flans*, which Cavanilles seems, by Swartz's work, to have first noticed, is supposed to differ from the *radicans*; but Willdenow asserts, on a comparison of numerous specimens, from different countries, that there is no specific distinction between them.

8. *W. dispar*. Various-leaved Woodwardia. Willd. n. 7. (Filix latifolia, pinnulis ferè acuminatis, dentata; Plum. Fil. 13. t. 16.)—Fronde pinnate; leaflets sessile, lanceolate, pointed, pinnatifid, with elliptic-lanceolate, entire lobes. Fructification crowded on the much smaller lobes, of a separate narrower frond.—Found by Plumier in Martinico. Willdenow appears to have adopted this species entirely from Plumier, a hazardous measure, as its genus can only be guessed from analogy. The barren fronds approach the last species in size, but their segments are shorter, entire, rather obtuse, and by no means taper-pointed. Those fronds which bear fruit have leaflets similar in shape and lobes to the others, but about one-third as large, at most, bearing a simple crowded row of fructification close to the rib of each segment. The groups of capsules are somewhat elliptical, and there is nothing adverse to the generic character of a *Woodwardia*; but, on the other hand, there is no particular indication of that character.

The root is described above an inch thick, and six inches in length; externally black, with several vermicular branching fibres, clothed with tawny or golden pubescence. Stalk of each frond near eighteen inches high, pale brown and smooth, leafy from its middle part to the summit, where it terminates in a large erect leaflet, constructed exactly like the rest, being equal in size to the larger lateral ones, and considerably exceeding those immediately below it. Such is the habit of *W. angustifolia*, but not of the other species in general.

WOODY Fibrous Matter, in Agriculture, that which is produced from small particles of different sorts of woody substances.

When merely formed of these parts, it is supposed to be the only vegetable matter that requires the aid of fermentation to render it nutritive to plants. The used bark of the tanner is a substance of this sort, which is very absorbent and retentive of moisture, but not penetrable by the roots of plants. See TANNERS' Bark.

Woody fibrous matter may likewise be prepared so as to become a manure, by the action of lime upon it.

It is observed in the “Elements of Agricultural Chemistry,” that as woody fibre consists principally of the elements of water and carbon, the latter being in larger quantities than in the other vegetable compounds, any process that tends to abstract carbonaceous matter from it, must bring it nearer in composition to the soluble principles; and that this is done in fermentation, by the absorption of oxygen and production of carbonic acid; and that a similar effect is produced by lime. See LIME.

WOODY Nightshade. See NIGHTSHADE.

WOODY Head, in Geography, a high cape on the coast of New Zealand, in the South Pacific ocean. S. lat. 37° 42'.

WOODY Island, an island in the East Indian sea. N. lat. 1° 46'. E. long. 106° 5'. See VICTOIRE.

WOODY Point, a cape on the west coast of North America. N. lat. 50°. W. long. 128° 5'.

WOODYCUTTY, a town of Hindoostan, in Canara; 8 miles E. of Onore.

WOOF, among *Manufacturers*, the threads which the weavers shoot across, with an instrument called the *shuttle*, between the threads of the warp, to form the web.

The wool is of different matter, according to the piece to be wrought. In taffety, both wool and warp are silk. In mohairs, the wool is usually flax, and the warp silk. In fattins, the warp is frequently wool, and the wool silk.

WOOFE, a name given in some parts of England to the sea-wolf, or *lupus marinus*; which see.

WOOGINOOS, in *Botany*. See BRUCEA *Antidy-senterica*.

WOO-HOO-SHIEN, in *Geography*, a town of China, in the province of Kiang-nan, near the river Yang-tse-kiang, a narrow cut leading from the river to the city, and flowing through the suburbs. This is a place of considerable trade; in the suburb there are several good dwelling-houses, apparently belonging to persons of distinction; and in the city itself there are many shops, which, it is said, would not disgrace the Strand or Oxford-street in London. These shops are spacious, consisting of an inner and outward compartment, and well supplied with articles of all kinds, both of raw and manufactured produce. The porcelain shops are particularly large, and contain great varieties of the manufacture. The main street leading directly through the city is not less than a mile in length. Several streets branch off from this, which are all paved, and contain good houses. The number of shops that are filled with lanterns of all descriptions, both horn and paper, indicate manufactories of those articles. The principal wall of the city extends on the north face; and the other is so overtopped with houses, that it almost escapes notice in passing down the main street, which it crosses. On the declivity of a hill to the northward are the temple and ancient tower. The temple, to which there is an ascent by a very steep stone stair-case, resembles that at Nankin, the god Fo being represented by the same attributes, and the principal hall being surrounded by similar figures of sages, in the same style. In another temple in the suburb there was a greater resemblance to that of Nankin. Woo-hoo-shien does not seem to be populous in proportion to the number of shops, and the quantity of accumulated produce exposed for sale. The suburb near the city contains several good shops, which were crowded with people. Ellis's *Journal of the late Embassy to China*, vol. ii. Lond. 1818.

WOJEDA, a town of Algiers, in the province of Tremecen, anciently called Guagida; 20 miles W.S.W. of Tremecen.

WOOL, in *Natural History* and *Manufactures*, Latin *lana*, *lanicium*, Fr. *laine*, signifies soft hair or down, more particularly that of sheep, but is applied to the soft hair of other animals, as of the vicunna, commonly called Vigonia wool, that of the yak of Tartary, &c.; and also to fine vegetable fibres, as cotton. The Romans applied the term extensively to the soft hair or down of all quadrupeds, and even to that of birds, as *lana anserina*, the wool or down of the goose; *lana caprina*, goat's-wool.

They also applied the term to vegetable substances:

—“*Nemora Æthiopiæ molli canentia lana.*”

Virg. Georg. ii. 120.

“The trees of Ethiopia, white with soft wool, or cotton.”

The distinction between wool and hair is rather arbitrary than natural, consisting in the greater or lesser degrees of fineness, softness, and pliability of the fibres. When they possess these properties so far as to admit of their being spun and woven into a texture sufficiently pliable to be used as an article of dress, they are called wool. The gradations between wool and hair on the skins of some animals are often too minute to admit of accurate distinction. The fleeces of many sheep contain fibres so hard and coarse, that they may most properly be called hair; and some hairy animals produce on part of their skins fibres possessing all the properties of wool; even in fleeces from the sheep, we may sometimes observe the very same fibre to be a coarse hair at one end, and at the other end a comparatively soft wool. The power of words, when inaccurately applied in retarding the progress of improvement, may frequently be traced in the most common occurrences of life, and we are persuaded it has had no inconsiderable effect in this instance, in preventing the cultivation of wool, in Europe, on the skins of other animals besides sheep. No one will deny that it is impossible to produce wool on the backs of the ox or the ass, if we restrict the term wool to the fleece of the sheep; but if by wool we mean a soft fine hair, possessing all the properties which render it suitable to be spun, woven, and fulled, to make cloth, the oxen of Thibet and the asses of Chili do produce and have for centuries produced such wool. Many of the asses and oxen even in this kingdom have soft woolly tufts of hair on some parts of their skins, and if such cattle were selected, and the breed cultivated, it is probable we might obtain from them a valuable addition to the materials on which national industry might be profitably employed.

Sheep's-wool appears to be the product of cultivation; we know of no wild animal which resembles the wool-bearing sheep. The argali, from which all the varieties of sheep are supposed to be derived, is covered with short hair, at the bottom of which, close to the skin, there is a softer hair, or down. (See ARGALI and SHEEP.) This is not peculiar to the argali; almost all quadrupeds inhabiting cold climates are covered in the same manner with a soft hair or down, which is protected by a coat of longer and coarser hair. By removal to a temperate climate, or when placed under the fostering care of man, and protected from the inclemencies of the weather, and supplied regularly with food, the coarse long hair falls off, and the animal retains only the softer and shorter hair, or wool. It is also observed that European sheep, removed to tropical climates and much exposed, soon become languid and sickly, and lose their fleece, which is succeeded by a covering of short coarse hair. Sheep in exposed situations in Europe often produce short coarse white hairs called kemps, intermixed with the finer wool; on removal to a warmer situation, and to a richer pasture, the coarse hairs fall off, and do not grow again. These facts are sufficient to prove the effect of cultivation on the fleece; and it must be observed that sheep's-wool of a good quality is never found but in those countries which have been the seats of the arts, and where a considerable degree of luxury or refinement exists, or has once prevailed. This is a strong presumptive proof that such wool has been originally obtained by a careful and long-continued attention to the selection of those sheep which produced the finest and most valued fleeces.

Angora, the ancient Ancyra, the former seat of arts and manufactures, still retains its breed of fine-woolled animals, among which the goat at the present time produces a fleece nearly equal to silk in lustre and fineness; and the cat and the rabbit of that district yet produce fine long wool. Damascus, and the other ancient cities of Asia Minor, preserve

in their vicinity the traces of the former cultivation of fine-woolled animals. The Tarentine fine-woolled sheep, so much valued by the Greeks and Romans, were obtained from Asia Minor, and were on that account sometimes called Asiæ. It is highly probable that these sheep came originally from the more eastern seats of luxury, where the soft fleeces are now grown, of which the shawls and cloths of India are fabricated.

In countries where manufactures have once flourished, their effects continue for a long time visible in the race of sheep which still remain there. Even in the present condition of the fleeces from Barbary and the adjoining states, the experienced eye may perceive the vestiges of a fine-woolled race of sheep, degenerated by utter neglect, in a climate naturally unfavourable to the production of fine wool. In Sicily and the southern parts of Italy, the remains of the ancient Tarentine breed preserve to the present day a race of fine-woolled sheep, but greatly degenerated by neglect. In Portugal the fine-woolled sheep retain more of their original purity, but are still much neglected. In Spain attention to the growth of fine wool appears never to have been entirely lost sight of, and it is here that the race of fine-woolled sheep exist in the highest degree of perfection, though, as we shall afterwards state, probably inferior in some important qualities to the original Tarentine race. Some writers have asserted that fine wool is the result of climate and food; but this is not the fact, though we admit that both have some influence on the quality of wool. It is the breed alone that primarily determines the fineness of the fleece; this has been ably demonstrated by the experiments of lord Sommerville, Dr. Parry of Bath, and others in this country, and by experiments on a larger scale in Sweden, Denmark, Saxony, and France.

It has been ascertained by Mr. Bakewell of Dishley, in Leicestershire, that the form of animals might be changed by selecting such as had any remarkable peculiarities, and continuing to breed from them for a few generations, when a new race is established, in which these peculiarities continue permanent. It has been ascertained by careful observations, both of cattle-breeders and physiologists, that in producing a new breed from two varieties of the same species, the female has more influence over the form of the progeny than the male; but with respect to wool the case is reversed, the quality of the fleece depending more on the sire than the dam. Beginning to breed from a coarse-woolled ewe and a pure fine-woolled ram, the produce of the first crosses will have a fleece approaching one-half to the fineness of that of the ram; and continuing to cross this progeny with a fine-woolled ram, equal to the first in quality, the fleece of the score and crosses will approach three-fourths to the fineness of the first, and in a few crosses more will be brought to an equal quality. If we state it numerically, and suppose the wool of the ewe to be twice as coarse as that of the ram, or as 320 to 160, the first crosses will have the fibre reduced to 240, the second to 200, the third to 180, the fourth to 170, the fifth to 165, the sixth to $162\frac{1}{2}$, which to all practical purposes may be regarded as equal to the first number. This ratio of approximation may be stated as correct on a large scale of experiment. If we breed with a fine-woolled ewe and a coarse-woolled ram, the series would be reversed, and in a few generations all vestiges of the fine-woolled race would be nearly, if not entirely, extinct. The ancient Romans, in the time of Columella, seem to have been fully aware of the effects of breed on the fineness of the wool, and as much as 200*l.* sterling was paid for a fine-woolled ram.

When a flock of fine-woolled sheep are once formed, they can only be kept pure by selecting and preserving the

finest-woolled rams, and most carefully avoiding all intermixture with sheep from coarser-woolled flocks that may exist in the country. Where this is neglected, the quality of the wool will soon be debased.

But supposing all the flocks in a country were of the fine-woolled race, accidental varieties of coarse-woolled sheep will occur among them, or of sheep having fleeces intermixed with coarse hair. If these be not carefully examined and removed, the wool will deteriorate, and more so where the climate is variable, and the sheep are exposed to great and sudden vicissitudes of temperature.

What has been stated may suffice to explain the circumstance of fine-woolled breeds of sheep being only found in the vicinity of present or ancient manufactures, or where they have been transported from such districts. Wherever fine-woolled sheep are neglected by man, the wool becomes either coarse, or intermixed with coarse hairs; the latter is the case in the Shetland isles, and in all countries where the arts and manufactures have been entirely destroyed, and ignorant barbarians have succeeded as the possessors of the soil.

Most ancient writers on wool, and even many moderns, seem not to be aware of any difference in wools, except the fineness or coarseness of the fibre; but the length of the fibre constitutes a far more important distinctive character. Long wool, or what is called combing-wool, differs more from short or clothing wool, in the uses to which it is applied, and the mode of manufacture, than flax from cotton.

Sheep's-wool may, therefore, be divided into two kinds. Short wool, or clothing-wool, and long or combing wool: each of these kinds may be subdivided into a variety of sorts, according to their degrees of fineness. This process is the proper labour of the wool-sorter.

Short wool, or clothing-wool, may vary in length from one to three or four inches; if it be longer it requires to be cut or broken, to prepare it for the further processes of the cloth manufacture. Short or clothing wool is always carded or broken upon an instrument with fine short teeth, by which the fibres are opened and spread in every direction, and the fabrics made from it are subjected to the process of felting, which we shall afterwards describe. By this process, the fibres become matted together, and the texture rendered more compact.

Long or combing wool may vary in length from three to eight or ten inches: it is prepared on a comb or instrument, with rows of long steel teeth, which open the fibres, and arrange them longitudinally: in the thread spun from combed wool, the fibres or filaments of the wool are arranged in the same manner, or similar to those of flax, and the pieces when woven are not subjected to the process of felting.

The shorter combing-wools are principally used for hose, and are spun softer than the longer combing-wools, the former being made into what is called hard worsted yarn, and the latter into soft worsted yarn.

Short Clothing-Wool.—The principal qualities deserving attention in clothing-wools are the regular fineness of the hair or pile, its softness and tendency to felt, the length and soundness of the staple, and the colour. The wool-buyer also regards as important the clean state of the fleece, and to the grower its weight is particularly deserving attention; for in fleeces equally fine, from sheep of the same size, some may be much heavier than others, the fibres of wool being grown closer to each other on the skin.

The fineness of the hair or fibre can only be estimated to any useful purpose, in the woollen manufacture, by the wool-sorter or wool-dealer, accustomed by long habit to discern

discern a minute difference, which is quite imperceptible to common observers, and scarcely appreciable by the most powerful microscopes. Of the various attempts that have been made to reduce the fineness of wool to a certain standard, by admeasurement with a micrometer, we shall afterwards speak. From some experiments we have made, as well as from those made by Mr. Luccock, Dr. Parry, and others, we may estimate the thickness of the hair of the finest Spanish and Saxony wool to be not more than the fifteen-hundredth part of an inch, and that of the finest native English to be from twelve to thirteen-hundredth parts, whilst the inferior sorts gradually increase to the six-hundredth part of an inch and more. A difference in the size of these fibres, too minute to be noticed by the common observer, may occasion a difference of 40 *per cent.* or more in the value of the wool. The fineness of the hair has been ever considered as an important quality since the clothing manufacture emerged from its rudest state. Fine wool was formerly valued because a finer thread could be spun from it, and a thinner fabric made, than from the coarser wools; but since recent mechanical improvements have been introduced into the woollen manufacture, it has been found practicable to spin coarse wools to the same length as the finer wools were formerly spun to. It is well known, however, to cloth-manufacturers, that whatever be the fineness of the yarn, unless the wool be fine, it is impossible to make a fine, compact, and even cloth, in which the thread shall be covered with a thick soft pile; nor would a thin cloth made from coarse wool have the same durability or appearance as one from fine wool of equal weight *per yard*. Fine wool will, therefore, always preserve a superior value to the coarse; indeed it was long considered as the principal and almost the only quality deserving the attention of the wool-grower, the wool-stapler, and the clothier.

The regular fineness of the fibre is also an object of considerable importance; the lower end of the staple, or that part of the fleece nearest the skin, will sometimes be very fine, and the upper part coarse. In some fine fleeces there will frequently be an intermixture of long, silvery, coarse hairs, and in other fine fleeces an intermixture of short, thick, opaque hairs, called kemps. When the wool is thus irregularly fine or intermixed, it is technically called not being *true grown*. The fine fleeces of Spain and Portugal, particularly of the latter country, are many of them injured by the intermixture of the long silvery hairs before-mentioned: whether this be owing to the original Tarentine breed having been crossed with the coarse-woolled native sheep of Spain, (see the article SHEEP,) and still preserving a tendency to revert to their first condition, or whether it be the effect of heat on the skin, is uncertain. The Saxony fleeces, from the same breed, removed to colder climates, are generally free from this defect. The coarse short hairs, or kemps, are not uncommon in some of the fine-woolled flocks of England and Wales, particularly those which are more exposed to the inclemencies of the weather, and have a scanty or irregular supply of food. It has been observed, in the first part of the article SHEEP, that in some flocks the proportion of fine wool in each fleece is much greater than in others, for in few or none is the wool grown uniformly fine over the whole body.

On the Merino sheep the fleece is more regular, whatever be the degree of fineness, than on any of our native English fine-woolled breeds. The Merino fleece admits of a division into four sorts, the *refina*, the *fina*, and the *tercera*, with a very minute portion of coarse from the shanks and head, which is not sent to market. The three sorts are distinguished in commerce by the marks R, F, and T.

On the average, there will be in each fleece nearly three-fourths of the best or R wool. The second and third sorts, or the F and T, will also contain a considerable portion as fine as the best; but being shorter and discoloured, or intermixed with coarse hairs, which require their locks to be separated from the best sort, or the refina.

In the native English fleeces, however fine some part may be, the proportion of the best sort rarely exceeds one-third part, and is frequently not more than one-sixth part of the whole fleece.

The value of the best part of a Spanish fleece, or the R wool, varies greatly in different flocks. When this sort, from the most esteemed flocks, may be worth six shillings and sixpence *per pound* in the English market, the R wool from another flock may not be worth more than three shillings and sixpence. The F and T wools are from 25 to 50 *per cent.* lower than the first sort: thus, the inferior sorts from the finest piles may be of greater value than the best sort or R wool of other piles; but they are never intermixed by the dealers, as they are applicable to different fabrics. In the English mode of wool-sorting, there will frequently be eight or ten sorts in a single fleece; and if the best wool of one fleece be not equal to the finest sort, it is thrown to a second, third, or fourth, or a still lower sort, which is of an equal degree of fineness with it. The best English short native fleeces, such as the fine Norfolk and South Down, are generally divided by the wool-sorter into the following sorts, varying in degree of fineness from each other, which are called,

Prime,
Choice,
Super,
Head,
Downrights,
Seconds,
Fine abb,
Coarse abb,
Livery,
Short coarse or breech wool.

Besides these sorts of white clothing wool, two and generally three sorts of grey wool are made, consisting of locks which may be black, or intermixed with grey hairs. Some wool-sorters also throw out any remarkably fine locks in the prime, and make a small quantity of a superior sort, which they call picklock. The origin of some of the above names is obscure, but the names of the finer sorts appear to indicate either a progressive improvement in the quality of the wool, or in the art of wool-sorting. The relative value of each sort varies considerably, according to the greater demand for coarse, fine, or middle cloths; and the variation during and since the late war in the Spanish peninsula has been much increased by temporary causes. Before that period, when the R wool of good Spanish piles sold at from five shillings and sixpence to six shillings *per pound*, the prime from Herefordshire fleeces was sold at about three shillings and sixpence, and that from the Norfolk and South Down from three shillings to three shillings and two-pence *per pound*. The higher price of the Herefordshire was in part owing to its being in a cleaner state. The Spanish wool is also cleaner than any of the English wools, being scoured after it is shorn; but the latter is only imperfectly washed on the sheep, previously to its being shorn. A pack of English clothing wool of 240 pounds weight, in its marketable state, will waste about 70 pounds in the process of the manufacture: the same quantity of Spanish wool, as sent to market, will not waste more than 43 pounds

on the average. This contributes to enhance the difference between the prices of each, as well as the superior fineness of the latter.

Different wool-sorters make a considerable variation in their modes of sorting the same kind of fleeces: some divide them into more sorts than others; but the following table will shew what may be taken as the average relative value of each sort, when the prime is worth about three shillings and two-pence *per* pound, and may serve to shew the skill required to estimate the value of fine English wool in the fleece.

	<i>s.</i>	<i>d.</i>		<i>s.</i>	<i>d.</i>	
Prime	-	3	0	to	3	4
Choice	-	2	4	to	2	8
Super	-	2	0	to	2	2
Head	-	1	8	to	1	10

} *per* pound in London.

The Softness of fine clothing Wool is next in importance to the fineness of the fibre, though it has been too little attended to in the culture of English wool. This quality is not dependent on the fineness of the fibre; it consists in the peculiar feel which approaches to that of silk or down, but in which the wool of all European sheep is inferior to that of Eastern Asia, or to the wool of the vicunna, or lama of Peru and Chili. In foreign European wools there are different degrees of this property, where the fibre is equally fine. In our native English wools, the like difference exists between the softness of wool possessing the same degree of fineness, but grown in different districts. In the harder wool, the fibre is elastic and hard to the touch, and cloth made from it has the same harsh feel; it is also more loose in its texture, and the surface of the thread is generally more bare. The difference in the value of cloth from two kinds of wool, equally fine, but one distinguished for its softness, and the other for the contrary quality, is such, that with the same process and expence of manufacture, the one will make a cloth more valuable than the other from twenty to twenty-five *per cent*.

Though the English woollen manufactures had been carried on for so long a period, the cause of this difference in cloths made from wool equally fine was but very imperfectly known till the present century. Mr. Robert Bakewell, then of Wakefield in Yorkshire, first directed the attention of wool-growers and manufacturers to this subject, in a work, entitled "Observations on the Influence of Soil and Climate

on Wool." The reason why the manufacturers remained so long ignorant respecting it arose, he observed, from the manner in which the woollen-trade had been carried on in Yorkshire, the great feat of the manufacture of English clothing-wool, the division of employment there not permitting the wool-dealer, or even the clothier, to witness the final result of the process. The wool-buyer in the distant counties, and the wool-sorter, who divided the fleece, were equally unacquainted with the cloth manufacture. The Yorkshire clothier sold his goods in an undressed, and often in an undyed state; they were bought and finished by the cloth merchant, who was formerly unacquainted with the previous processes of the manufacture, or the qualities of wool. In a promiscuous lot of undressed cloth bought at the same price, and apparently of the same quality in the rough state, if some pieces were finished much better and softer than others, it was attributed to lucky chance, the patron divinity of the ignorant. Mr. Bakewell proved that the hardness of English wools does not depend on the nature of the food, or even entirely on the breed; it is the effect of the soil acting on the surface of the fleece. The wools from chalk districts, or light dry calcareous soils, have the natural yolk or moisture absorbed by the particles of calcareous earth that penetrate the fleece, and the wool is thereby rendered hard. The same effect is produced on a skin where lime is used; it may also be produced by keeping wool for a longer or shorter time in a dry hot temperature; and when wool has been so dried, no process will restore to it its pristine softness. On the contrary, wools grown on rich loamy argillaceous soils are always distinguished for their softness. The quantity of grease or yolk in the fleece has a considerable degree of influence on the softness of Merino wool, the pile being so close as in a considerable degree to prevent the earthy particles from penetrating the fleece; but in all English fleeces the wool is grown thinner on the skin, and admits the more easy access of the absorbent particles. Exposure to the direct rays of a summer sun has also a tendency to injure the soft quality of the wool. We shall have occasion to refer to the methods recommended by Mr. Bakewell to improve the softness of wool on soils naturally unfavourable to its growth.

Of fine European wools, the Saxony generally possesses a greater degree of softness than the Spanish, which we believe to be owing to the sheep being less exposed to the action of light and heat. The native fine Italian wool, before the introduction of the Merino race, possessed a considerable degree of softness, judging from wools which we have seen from thence, but they were deficient in soundness, and not *true grown*. The wools on the chalk soils in the southern and eastern side of England are generally hard, except, as in Kent, where the chalk is covered by thick argillaceous beds. Nottingham forest, Chamwood forest in Leicestershire, and some parts of Shropshire, produced not the finest, but some of the softest wools in England before the late inclosures. The Cheviot hills in Cumberland are not pastured by the finest-woolled English sheep, but their fleeces possess a degree of softness exceeding any from the other districts of England, and they are rendered soft by artificial means, which we shall describe. It is still somewhat uncertain, whether there are two distinct breeds of sheep, from which the fine shawl wool of India are grown; or whether one species of the animal which yields it is not to be classed with the goat. The fleeces from India, which we have seen, are grown on a very small sheep; close to the skin, there is a wool as soft as the softest fur; this is covered by long coarse hairs growing through it. When the wool is once shorn, the separation of these hairs from the soft wool

wool is a work of extreme difficulty; but on the back of the sheep we believe the separation can be made with great ease. The softness of the Indian wool is not even distantly approached in the very softest Merino fleeces from Saxony and Spain; this may be proved by comparing the finest cassimere cloth from Saxony wool, with the shawls or shawl-cloth of India. The ancient Tarentine sheep, called by way of excellence 'molles oves,' were treated with peculiar care by the Romans, and clothed in skins, which we believe was intended to preserve the softness of the wool, as it is still practised in some parts of Asia for that purpose. In Europe no experiments have been made directly to improve the softness of wool, though wool approaching in softness to that of India would be a most valuable acquisition to our manufactures. To be convinced of this, it need only be stated, that the yarn from Indian wool has been sold here at three guineas *per* pound, not on account of the superior fineness of the spinning, but for the softness of the wool. For coarse goods, indeed, such as blankets, carpets, and cloths called duffields, raised with a hairy pile, a considerable degree of hardness or elasticity of the fibre is an advantage; but in all the finer articles of the woollen or worsted manufacture, the opposite quality is of great value.

The felting property of wool is intimately connected with its softness, the softest wools having the greatest tendency to felt, and the hard wools are all defective in this respect. The felting property appears to depend on a peculiar structure of the surface of the fibres, by which they are disposed to move in one direction more easily than another. This is perceptible in drawing a hair through the fingers, first from the end to the point, and again from the point to the end; in one direction the hair feels perfectly smooth, in the other direction a peculiar roughness is felt. The cause of this is supposed to be owing to the surface of the fibres having laminæ, like the scales of fishes, with the edges laid over each other. Indeed in the furs of some animals we have observed with a powerful microscope, that the surface is composed of laminæ laid over each other, resembling the arrangement of the leaves of the artichoke. On this property the process of hat-making depends; the short fibres of the fur being repeatedly compressed, move and interlock with each other, so as to form a compact substance; this motion is further aided by heat and moisture. A similar process takes place to a certain degree in cloth subjected to the strokes of a fulling-mill; the fibres cohere, and the piece contracts in length and breadth, and its texture is rendered more compact and uniform. This process is essential to the beauty and strength of woollen cloth; and it is observed, that the softer wools felt in much less time than the harder, and form a closer pile on the surface of the cloth, on which account it is a common practice to mix a certain quantity of soft wool with the hard, to enable the former to felt with more facility.

The length and soundness of the staple of clothing wool is the quality next to be considered. By the staple of wool is meant the separate locks into which the fleece naturally divides in the skin, each lock consisting of a certain number of fibres, which collectively are called the staple.

The best length of staple for fine clothing-wool, if found, is from two to three inches. If it be longer it requires breaking down to prepare it for the process of carding. Saxony wool, being generally more tender than the Spanish, and more easily broken down, is sometimes four or five inches long; but as it works down easily, it is preferred, on account of the length of its staple, for such goods which

require fine spinning, as cassimeres, pelisse cloth, and shawls. Much of the English clothing-wool of a middle quality is grown longer than is desirable for the purpose of the clothier, and when found is thrown out for the hosiery trade, if the demand for the latter be great. As the grower could not shorten the length of the staple without diminishing the weight of the fleece, he has no motive to induce him to grow shorter wool; but the object might be obtained with much benefit to himself by shearing twice in the year, once the latter end of April, and again the latter end of August; the wool would then be grown of a suitable length for the card, and from experiments that have been made we believe the weight would exceed what can be obtained from one clip: the increase would not be less than fifteen *per cent.*, and the condition of the sheep thereby improved.

The soundness of the staple in clothing-wools is not so important as in combing-wools; but for some kinds of colours which injure the wool, it is particularly desirable that the fibre should be sound and strong; this is judged of by drawing out the staple and pulling it by both ends. The soundness and strength of the staple depend primarily on the healthy state of the animal, and on a sufficient supply of food. The staple on some parts of the fleece will always be more tender than on other parts, but by mixture they tend to form a dense pile on the surface of the cloth.

The colour of the fleece should always approach as much as possible to the purest white, because such wool is not only necessary for cloths dressed white, but for all cloths to be dyed bright colours, for which a clear white ground is required, to give a due degree of richness and lustre. It is probable that all sheep's-wool was first of a black or reddish colour: the latter is often referred to by the ancients. Before the invention of dyeing, coloured wool must have had a preference to white; but after the act of communicating beautiful colours to the fleece, white wool would be in the greatest demand, and those sheep which had white fleeces would be selected to breed from. The most ancient flocks of sheep which we have any record of are those of Laban and Jacob, described in the book of Genesis. The fleeces appear to have been principally brown, or spotted and striped, which was in all probability the general colour of the flocks throughout that part of Asia. We learn that in the course of twenty years a great change was effected in the colour of a large portion of the sheep of Laban: though Jacob appears to have concealed from his father-in-law the method by which this change was effected, we are expressly told in the sequel that it was by crossing with rams which had fleeces of the colours required.

Dark-brown or black woolled sheep are not uncommon in many parts of the European flocks, but such wool being of less value than the white, these sheep ought always to be expelled. Some of the English fine-woolled sheep, as the Norfolk and South-Down, have black or grey faces and legs. In all such sheep there is a tendency to grow grey wool on some part of the body, or to produce some grey fibres intermixed with the fleece, which renders the wool unfit for many kinds of white goods; for though the black hairs may be too few or minute to be detected by the wool-sorter, yet when the cloth is stoved they will become visible, forming reddish spots, by which its appearance is much injured. The Herefordshire sheep, which have white faces, are entirely free from this defect, and yield a fleece without any admixture of grey hairs. We have no doubt that by carefully rejecting those sheep from the South-Down flocks, in which the grey is most apparent, this defect might be gradually removed. It is particularly desirable with respect

to these sheep, as the wool grown on chalk soils, though less soft than on other soils, is generally whiter, and better suited to such goods which require the process of bleaching or stoving, and do not require to be so much fulled as many other cloths.

The ancients were so well aware of the necessity of expelling dark-coloured wool from their flocks, that in selecting the sheep to breed from, they did not trust to the colour of the fleece alone, but carefully examined the mouth and tongue of the ram, and if the least blackness or swarthiness appeared he was immediately rejected; and though some moderns have doubted the use of this precaution, we believe it was well founded.

“ Illum autem, quamvis aries sit candidus ipse,
Nigra subest udo tantum cui lingua palato,
Rejice, ne maculis infuscet vellera pullis
Nascentem.” Vir. Georg. iii.

Pliny also states, that particular attention was on this account had to the colour of the mouth. “Arietum maxime spectantur ora.” We are informed that this kind of inspection takes place in the Spanish flocks at present, a practice in all probability derived from the Roman shepherds, as we believe the flock to have been from those of Italy, or the Tarentine breed. The colour of the soil on which sheep graze, if very dark or red, communicates to the wool a tint more or less strong, which is indelible, and renders such wool less proper for cloths or hosiery goods that are to be finished white; for though the colour may be improved by stoving, yet on washing the cloths, they soon return to a brownish or yellowish tint. The tint from the soil is, however, rarely of sufficient strength to be regarded for dyed goods, excepting for exceedingly light colours.

The cleanness of wool is principally regarded by the purchaser, as it affects the weight. To the grower those fleeces are generally the most profitable that are well filled with the grease, or yolk as it is called, because it keeps the wool in a sound state, and improves its softness. It ought, however, to be washed out as much as possible before it is exposed to sale. The fleeces of the Merino sheep are more plentifully supplied with yolk than those of any of our native fine-woolled breeds; indeed it is so abundant, that the English mode of washing on the back of the sheep will scarcely produce any effect upon the fleece. The yolk or grease in the fleece appears, from the experiments made upon it by M. Vauquelin, to be a native soap, consisting principally of animal oil combined with potash. It is most copiously produced in those breeds which grow the finest and softest wool, and is always most abundant on those parts of the animal which yield the finest parts of the fleece. To this subject we shall again refer in treating of the improvement of wool. This yolk, though so beneficial to the wool in a growing state, becomes injurious to it when shorn; for if the fleeces remain piled in an unwashed state, a fermentation takes place, the yolk becomes hard, and the fibre is rendered hard and brittle. This effect takes place more rapidly in hot weather. The Spaniards remove this yolk in a great measure by washing the wool after it is shorn and sorted. In Saxony fine-woolled sheep of the same race are washed in tubs with warm water, soap-lees, and urine, and afterwards in clean water.

In England the wool is washed on the back of the sheep by immersing the animal in water, and squeezing the fleece with the hand. From these different modes of washing, the wool is left more or less pure. Mr. Bakewell, in his Ob-

servations on the Influence of Soil and Climate on Wool, has given the following table, containing a statement of the quantity of neat wool in every hundred pounds, taken on an average of each sort, and supposing each to be free from lumps of pitch employed in marking the wool, and cleared from what are called the *dog-locks*. The first column represents the average weight after the wool has been scoured perfectly clean with soap and water, and dried; the second the amount of waste.

	Pure Wool.	Waste.
100 lbs. of English wool washed on the sheep's back	75	25
Ditto Saxony fleece-wool	80	20
Ditto Spanish R, or refine	88	12
Ditto Spanish and Portugal unwashed	75	55
Ditto English fleeces unwashed	60	40
Ditto lightly greased wools of Northumberland washed on the sheep's back	65	55

Hence it is obvious, that the state of the fleece with respect to cleanness is an object of great importance to the wool-buyer. The English Merino sheep, from the difficulty of washing the wool on the sheep's back, have generally been shorn in an unwashed state, and the wool offered for sale in this state. The purchasers were frequently unacquainted with the great amount of the loss it would suffer by washing, and were much disappointed at the result. This circumstance, we conceive, more than any other, tended to prejudice the manufacturer against the Anglo-Merino wool. The wool is also injured by remaining in the grease, as we have before stated, and though this has been contradicted, we have no hesitation in asserting the fact from our own experience. Indeed the French manufacturers of fine cloth assert, that the best wools from Spain, though cleared in a great measure from the yolk, yet still retain sufficient to injure the wool if it be suffered to grow old when it is packed, the yolk becoming rancid and hard, and communicating the latter property to the wool. We have frequently observed this effect in the wools from Portugal, that retain a greater portion of the yolk than those from Spain.

After wool has been washed in the usual manner practiced in England, and piled or packed, a certain process takes place in eight or nine weeks, called *sweating*. This is well known to wool-dealers and manufacturers, but has not been before noticed by any writer that we are acquainted with. It is evidently an incipient fermentation of the remaining yolk; and the inner part of the pack or pile becomes sensibly warm. This process produces a certain change in the wool, whereby it becomes in a better condition for manufacturing, being what is called in the north of England less *fuzzy*. This effect results from a diminution of the natural elasticity of the fibre.

When this fermentation takes place in unwashed wool, it proceeds farther, and injures the colour and soundness of the staple or fibre. A similar effect is produced in wool or cloth which has been oiled, and remains some time in an unscoured state. Instances of spontaneous combustion from heaps of refuse wool remaining in a greasy state have been known to occur, and occasion the most serious accidents in woollen factories.

The weight of the fleece is an object of great importance to the grower. It is generally supposed by the English wool-dealers, that an increase of weight implied an increase of coarseness; indeed the words coarse and heavy are considered by them as synonymous, but this is not absolutely

WOOL.

The method of measurement adopted by Mr. Luccock might be sufficiently correct with the deduction of one-fifth, were the instrument always used by the same person, and a similar degree of pressure given in each experiment; but as this is required, it becomes uncertain in its results, and inadequate to practical purposes.

Dr. Parry's method of measurement is effected with an instrument similar in principle to the lamp micrometer of Dr. Herschel, of which an account is published in the Philosophical Transactions for 1782. (See MICROMETER.) An object of a known diameter being placed in the focus of a compound microscope, and strongly illuminated, a piece of white paper is placed horizontally at some distance beneath it; then looking through the microscope with one eye, and keeping the other steadily open, you will see the object apparently projected on the paper, which is to be measured, whilst viewing it, with a pair of compasses. Divide the length of the image so measured with the known diameter of the object, which will give the magnifying power of the microscope. This being found, place the object you wish to measure in the focus, and projecting its image on the paper as before, measure it with the compasses, and divide the result by the magnifying power, which will be the real magnitude of the object required.

The light of a lamp is to be preferred to day-light, and the fibres to be measured are to be stretched on a glass, and waxed down at both ends. The under side of the glass should be blackened with Indian ink, except in three parts, the middle, and near the two ends. The unblackened spaces being placed in the focus of the microscope, ten or more filaments may be examined and measured successively, both in the middle part of the glass, and near the ends, which will give the diameter of the filament at the upper and lower end of the staple, and in the middle. Each lock of ten filaments being thus examined in three different parts, the mean of the three measurements must be taken for the mean diameter of each filament, and the mean diameter of the ten filaments may be taken for the fineness of the whole lock.

In place of the blackened glass, we would recommend a thin slide of ivory or brass, about five inches in length, and half an inch in breadth, with three transverse slits or openings, one in the middle, and the two others about three-fourths of an inch from each end. On this slide the filaments may be stretched, it will not be liable to break, and the edges of the filaments will be more correctly defined than when a plate of glass is placed under them.

The farther the paper is removed from the eye, the larger will be the apparent space covered by the image of the object, but it must not be too far for the hand to measure it with compasses. But if in place of the compasses we have a sheet of pasteboard graduated into minute divisions from a black line upwards, and a sliding index be adjusted, the pasteboard may be placed at a much greater distance, the observer adjusting the slide, until the edge of it and the black line coincide with both edges of the filament. An

the case; a fleece grown upon the same animal may be increased in weight either by the fibres becoming coarser, or by their being grown longer, or by a greater number of fibres being grown in the same skin. To the wool-grower it can never answer to increase the weight of the fleece on small fine-woolled sheep, by growing the wool coarser; if this be his object, the long-woolled breeds of sheep are to be preferred. He may produce wool somewhat longer by increasing the quantity of food; but it generally loses something of its fineness, and is less suitable for the cloth trade. He may, however, increase the weight considerably by selecting such breeds as grow the wool close upon the skin, and are thickly covered with wool over every part of the body. In this respect, the Merino sheep have greatly the advantage over any of the native breeds of English sheep; many of them yielding from three to four pounds of pure wool, whilst the finest English fleeces rarely exceed two pounds, and would lose one-fourth of this weight when brought to a pure state by scouring. It has been doubted whether all sheep's-wool, when clean, possesses the same specific gravity; but admitting there may be some variation in the wool from different piles, we conceive that it is too minute to deserve the attention of the wool-grower or manufacturer.

The filaments of fine wool being so minute, it requires an eye habituated by long experience to appreciate the relative fineness of two piles, which may differ in value as much as twenty-five per cent. Even those who have been long practised in such examinations find it difficult to form immediately a correct opinion of the fineness, if they are removed for a few weeks from all opportunity of viewing wool. It is not surprising then that the wool-grower, who only directs his attention to the subject during one part of the year, should often be unable to judge whether his wool has improved or not since the preceding summer. On this account it would be highly desirable that some easy and correct method of admeasurement by the micrometer could be invented, which might enable the observer to decide this with certainty. Mr. Daubenton employed a graduated scale, adapting it to the eye-piece of a compound microscope; but his method does not admit of accuracy. Mr. Luccock made use of a more simple instrument, which we have seen; it consisted of a lens about half an inch in focal length, adjusted to a graduated scale. On this scale a number of fibres were stretched and compressed by a slider and screw into a given space; the filaments covering this space were then counted by the aid of the lens, and a number of admeasurements being taken of the same sort, the mean of the whole was supposed to give the correct diameter of the filament. In this method, however, some of the filaments must unavoidably overlap part of the others, on which account a greater number will be seen in a given space than there would be were the whole diameter of each fibre visible. The error resulting from this may be stated at one-fifth. Thus Mr. Luccock makes the best English wool to measure the fourteen-hundredth part of an inch, which is finer than the best Spanish, as measured by Dr. Parry, by a more accurate but more laborious method. According to Mr. Luccock, a sample of moderately fine Spanish wool reached to the sixteen-hundredth part of an inch; according to Dr. Parry, the very best Spanish is not smaller than the fourteen-hundredth part of an inch.

With the above deduction of one-fifth, which we believe to be a near approximation to correctness, the diameter of the fibres of the best English wool, as sorted in the usual method, will be nearly as follows:

horizontal position for the microscope will be the most convenient, illuminating the object with a lamp and lens. In this way, the apparent diameter may be greatly increased, and we think the observations might be made with greater ease and accuracy.

By the above method the diameter of very minute filaments may be ascertained, and minute differences detected, which the unassisted eye is unable to detect. We are aware, however, that it requires some address and time to enable the observer to manage the instrument, on which account it cannot, we fear, be made generally useful.

The following admeasurements of different fine wools were taken with Dr. Parry's instrument; the first column represents the outward end of the filament, the second the middle, and the third the bottom, in fractional parts of an inch; the latter column the mean of ten filaments of the same wool.

TABLE of comparative Diameters of the Filaments of various Clothing Wools, by Dr. Parry.

Long Wool, or Combing Wool, being prepared for spinning by a process entirely different from that of short or clothing wool, and the pieces made from it being finished in a very different manner, the qualities most required in this kind of wool are length and soundness of the staple, without which the fleece is unsuited for the comb. The fineness of the hair is a secondary quality, required only in certain kinds of goods. The wool-comb is an instrument of simple construction, consisting of a wooden handle, with a transverse piece or head, in which are inserted three rows of long steel teeth. The wool, which is to be combed after being clean scoured, dried, and oiled, is first drawn upon these teeth with the hand, until the comb is sufficiently loaded. It is then placed on the knee of the comber, and another comb of a similar kind is drawn through it, and the operation is repeated till all the hairs or fibres are combed smooth in one direction. This operation requires considerable strength, but the comb being previously heated, and the wool thoroughly oiled, facilitates the process. When completed the

combed wool is drawn off with the fingers, forming what is called a *sliver*; the shorter part of the wool sticks in the teeth of the comb, and is called the *noyl*: this is fold to the clothiers.

From the above description, it is evident that if the staple of the wool be not found, the greater part of it will be broken by the process of combing, and form noyls. The staple must also have a sufficient degree of length for the combs to operate upon it. Length and soundness of the staple are therefore the most essential and characteristic qualities of combing-wools.

Long wools may be classed into two kinds: first, those suited for the manufacture of hard yarn for worsted pieces; and second, those suited for the manufacture of soft yarn used for hosiery. The former require a greater length of staple than the latter. The first may therefore be called long combing-wool, and the latter short combing-wool; between these there are gradations of wool, which may be applied to either purpose.

Long combing-wool should have the staple from six inches to eight, ten, or even twelve, in length. Before the recent improvements in spinning by machinery, a very great length of staple was considered as an excellence in long combing-wools; and on this account the hog-wool, or the first fleeces from sheep which had not been shorn when lambs, was more valuable than the wether wool from the same flock, and bore a higher price than the former, by at least fifteen per cent. Since that time the wether wool has risen in relative value on account of the evenness of the staple, each lock being nearly equally thick at both ends; but the staple of hog-wool is pointed, or what is technically called *spirey*. Eight inches, if the wool be found, may be regarded as a very proper length for heavy combing-wools. The longer stapled wool was formerly worked by itself, and used for the finer spun yarn, or mixed in small quantities with the wether wool, to improve the spinning. It is found that an equal length of staple contributes to the evenness of the thread when spun by machinery, and a very great length of staple is rather injurious than otherwise in the process of machine spinning. To the wool-grower, however, it must always be desirable to increase the length of his heavy combing fleeces, as he thereby materially increases the weight; and we have not yet learned that the price has ever been reduced on this account, for if the wool be too long for some branches of the worsted manufacture, there are others in which it may be worked with advantage.

The length of the staple may be increased by a plentiful supply of nutritious food. The same effect may also be produced by letting the wool remain a longer time on the sheep before it is shorn. We have seen a staple of Lincolnshire wool which was twenty inches in length: it had grown two years without shearing. This, however, would be unattended with any advantage to the grower. The more frequently sheep are shorn, provided the wool is sufficiently long, the greater will be the weight grown in a given time on the same animal; for, from observations which we have made, we are satisfied that wool is grown more rapidly immediately after the sheep are shorn than at any other time. Length of staple in wool depends primarily on the breed, but may be more affected by culture than many other qualities of the fleece. The soundness of the staple may be easily judged of by pulling both ends of it with the fingers with considerable force. In weak or unsound wool the staple easily breaks in one or more parts, and on observing it, it will be seen that the fibres are much thinner in the part which breaks. This is occasioned either by a deficient supply

ly of food, by disease, or by inclement seasons, which cause a stoppage in the growth of the fleece. This goes on to a greater or less degree. In some instances, the stoppage has been so entire that the upper part of the staple is nearly separated from the lower, and is only connected with it by a few filaments: in such cases, the stoppage has continued for a considerable time, and the bottom part of the staple may be considered as a new fleece, protruding the old one from the skin. Connected with the soundness of wool, there is another property required; this is, that the staple be free and open, or that the fibres shall not be matted or matted together; an effect which takes place frequently when the wool is unfound. It is in fact a natural felting of the wool on the back of the animal, when by any cause it has ceased to grow. Sometimes the lower part of the fleece next the skin will be so completely matted as to form a substance nearly as hard as a hat, and will hold to the skin by a few hairs only. These are called cotted fleeces; all approach to this state is peculiarly injurious to combing-wools. The wool-buyers generally throw out the cotted and unfound fleeces when they pack the wool from the grower, and buy them at a very reduced price. The softness of combing-wool, though of less importance than in clothing-wool, yet enhances its value, as it is found that such wool makes a closer and softer thread, and in every process of the manufacture finishes more *kindly*. Combing-wools grown on light calcareous soils are deficient in this respect; such are the combing-wools of Oxfordshire and the Cotswold hills, which are formed of that species of lime-stone called oolite, or roe-stone. A copious supply of the yolk is necessary to the healthy condition of the fleece, and as this in many locks is nearly equal in weight to the wool, the fleeces contain from six to eight pounds or more of it before they are washed, for in the unwashed state they often weigh eighteen pounds in many of the long-woolled flocks in England.

The whiteness of the fleece is less important in the long combing than in clothing wool, provided it be free from grey hairs. The latter circumstance does not frequently occur in combing-wools. There is, however, a peculiar colour communicated by the soil, which is sometimes so deep as to injure the wool for particular uses, and what is of more importance, there is a dingy-brown colour given to the fleece by impoverished keeping or disease, which is called a *winter stain*; it is a sure indication that the wool is not in a thoroughly sound state, and such fleeces are carefully thrown out by the wool-sorter, being only suited for those goods which are to be dyed dark colours.

The fineness of heavy combing-wool is of less importance than the other qualities. In every fleece of this kind there will be a certain small portion of short clothing-wool on the flanks, the belly, the throat, and the buttocks. The clothing-wool from such fleeces is not often divided into more than two or three low sorts, and the combing-wool is seldom thrown into more than four sorts, that is, two sorts of the hog-wool, and two sorts of the wether-wool, of which three-fourths, if the fleece be good, will form the best sort in each.

There is, however, a fine long combing-wool which is required for bombazines and the finer kinds of worsted goods; this is most frequently selected from the longer parts of clothing fleeces, and admits a division into four or five sorts, the finest being equal in hair to that of the head or super in clothing-wool; whereas the best sort of the common heavy combing-wools seldom ranges higher in point of fineness than the coarsest sort of clothing-wool above the breech locks; *viz.* the low abb and the livery.

Short combing or hosiery wool requires a different length of staple, according to its fineness: for the better sorts, the staple should not be shorter than four or five inches; the lower sorts may range as high as eight inches. A greater length than this is not desirable for any kind of soft worsted. What has been said of the soundness and fineness of staple required for long combing-wool, applies equally to the hosiery wool, but in this the fineness of the hair and softness are of more importance. Most of the fleeces which yield fine combing-wool produce nearly an equal quantity of short wool, which is thrown in the same manner as the regular clothing sorts. The combing sorts for the hosiery are generally called,

Super matching,
Fine matching,
Fine drawing,
Altered drawing,
Brown drawing,
Saycast.

The names of these sorts derive their origin from ancient processes of the manufacture, with which we are unacquainted at present. The lower sort, or saycast, was probably at first the long coarse combing-wool, thrown out for the manufacture of says, of which we have frequent mention in the earliest history of the woollen trade in England. The relative value of these sorts, compared with each other, varies according to the demand for the finer or coarser kinds of hosiery, and is also affected by the clothing trade. When any clothing sort which ranges in fineness with one of the combing sorts is in great demand, the wool-sorter will break down the shorter combing-wool of this sort, and throw it to the clothing-wool, which enhances the price of the former by making it scarce. The fineness of these sorts out of the best combing-wools, stated numerically, as compared with clothing sorts, will be nearly as under, in the fractional parts of an inch.

Most of the best sorters throw out the hog combing-wool from the best sorts, making a superfine hog for the bombazine trade, hog-wool being less suitable for the hosiery, which does not require yarn so finely spun as for hard yarn.

As all the different sorts of short combing-wool, together with several sorts of clothing-wool, will frequently occur in one English fleece, it is obviously the interest of the grower that his fleece should produce as great a proportion of the best sorts as can be done without materially diminishing the weight.

Skin Wool, or Pelt Wool, is the wool separated from the skins of slaughtered sheep by the fellmonger. The quantity of this wool, in a country like England, where so much animal food is consumed, is very considerable, and has been estimated at near 50,000 packs of 240lbs. *per annum*, for England and Wales. Soon after shearing, the skin-wool is too short to be worked by itself, and is generally kept and mixed in with the longer wools. The process by which wool is separated from the skins has a tendency to make it hard, and destroy or injure its felting or milling property, on which account short-skin wools are seldom used for the manufacture of cloth, but more generally for flannels, serges, and those kinds of goods which require little or no milling;

the finest kinds are much used for stockings made of yarn from carded wool. In the spring, when the wool on the skins has acquired a considerable length, it is thrown into combing sorts; the finer kinds are used for knitting hosiery yarn, and the coarser for hard yarn for the warps of serges and other goods, having a warp of combed and a weft of carded wool. The value of skin-wool is seldom equal to that of fleece-wool of the same degree of length and fineness, owing to the felting property being injured, which renders it more unfit for the manufacture of woollen cloth.

Lamb's Wool.—The wool of the lamb is, with certain exceptions, softer than that of sheep's-wool, from the same flocks. It possesses the property of felting in a remarkable degree, and on this account is principally manufactured into hats, except skin lamb's-wool, which losing its felting property in a great degree, is employed in the manufacture of flannels and woollen yarn for lamb's-wool hosiery. In the northern parts of Europe, the lambs of some of the breeds of sheep possess a fleece so delicately soft, that it constitutes a most valuable fur, being dressed on the skin, and used as a costly article of attire. According to Pallas, the inhabitants of the Ukraïn and Podoli, as soon as the lamb is dropped, (which comes into the world with a pretty wavy skin, even without the assistance of art,) to augment its beauty, and make it bring a higher price, sew it up in a sort of coarse linen shirt, so as to keep up a constant gentle pressure on the wool, pouring warm water over it every day to make it soft and sleek; only letting out the bandage a little from time to time as the animal increases in size, but still keeping it tight enough to effect their purpose, which is to lay the wool in beautiful glossy ringlets, and thereby produce a delicate species of fur in great request for lining clothes and morning-gowns. By this treatment, the staple of the fine soft wool which rises in the infancy of the lamb takes a handsome arrangement; and the animal is killed younger or older according to the species of fur intended to be produced; from a short glossy nap, like satin, only fit from its thinness for the purpose mentioned above, to a warm thick fur for a winter great-coat. The first of these furs in estimation and price is a fine black, that looks like silk damask; an inferior black fur comes next, much thicker, used for *pelisses*, or *shubes*, as the upper winter garb worn out of doors is called; and the least in estimation is the whitest, except it be of a very pure colour and silky appearance, where it is a rival to the first; especially for night-gowns, a very common dress both morning and evening amongst the Russians; particularly in the interior parts of the empire.

The Boucharian sheep, as described by Pallas, grows a compact, soft, and elastic wool, which is elegantly formed into frizzled ringlets. In the lamb, the wool is formed into delicate little circular waves, as if pressed close to the skin by art; but when taken from the mother, or killed immediately after birth, they are still more beautiful, and often elegantly marbled with feathered waves, like silk damask. These three furs are the finest and most precious of the kind known to Europe and the East; they are brought to us by the Boucharian Tartars and Persians, who sell them dear. The most prized are, the *blue*, the black, and the silver grey; but of the *unborn lamb-skins*, as the fine glossy thin furs are called, which so much resemble silk damask, the fine black is dearest and most esteemed. To obtain these valuable furs, the Boucharian Tartars purchase whole flocks of male lambs just dropped from their mothers: as to kill a female till past the age of breeding is held as a kind of crime by all Tartar hordes; such is their reverence for an animal which constitutes their greatest riches, and the propagation and care of

which are the great business of their lives; so that all the fur we see of this species sold by the Tartars are from young rams. The Boucharians are of opinion, that art is necessary to preserve these furs in their greatest beauty; and under that idea, keep the lambs under shades, &c. during the meridian ardour of the sun; but Dr. Pallas has reason to think, that these precautions are useless, as he observed that the same variety of sheep produced the same fine hues equal in every respect, without any sort of care, in the hands of the Kirguite Tartars.

It is very remarkable that the lamb's-wool, in many of the Merino flocks, is coarser than the sheep's-wool. In some of the flocks, the lambs are at first covered with coarse hair, which falls off afterwards, and they produce the finest wool.

Wool from other animals besides the sheep is employed in manufactures, and spun and woven into fabrics of different kinds, either unmixed or mixed with sheep's-wool. The goats of Thibet, which grow the fine shawl wool, produce it as a fine down at the bottom of the long coarse hair, with which the animals are covered. Many of the common goats in Europe grow a similar down, which, by cultivation, might become a valuable article of commerce. It is not, however, yet clearly ascertained, whether the shawls and shawl cloth of India are all manufactured from goat's-wool; part of it appears to be made from sheep's-wool peculiarly soft and fine. The Angora goat grows a hair extremely fine and silky, which is much used in some of the French worsted goods mixed with silk. This goat is properly a long-woolled animal. Dr. Anderson says, that the Angora goat will prosper and preserve its peculiarities in France and Sweden. The wool of the vicunna, called Vigonia wool, is generally of a reddish-fawn colour; it is peculiarly soft and silky, but intermixed with long coarse hairs, which are very difficult to separate. (See VICUNNA.) From the lama and pacos of Peru a stronger and longer stapled wool is obtained, which is sometimes white. Under a liberal government which protected and encouraged commerce, we have no doubt the fleeces of these animals might be greatly improved, and would become an article of great value. The wool from the yak of Tartary, and the mulk ox of Hudson's bay, has yet received little attention. We have seen stockings made of the latter, and which are worn in that country; the wool was soft but not fine, and much intermixed with long coarse hairs.

The quantity of sheep's-wool annually grown in England and Wales was estimated, by persons in the wool trade examined before the house of commons in the year 1800, at six hundred thousand packs. Mr. Luccock, in his Treatise on Wool, seems to consider this estimate as greatly exceeding the real amount, and has given an estimate founded on the supposed extent of surface pastured by sheep, and the quantity of sheep *per acre* in each county. This table we subjoin, as the only attempt that we know of to determine the question on certain data; though we consider it only as an approximation to truth, and are inclined to believe that the quantity is under the real amount. Such is also the opinion of the most intelligent persons in the wool trade, whom we have had an opportunity of consulting.

From this table, it will appear that the total amount, including skin-wool and lamb's-wool, is somewhat short of four hundred thousand packs, which is probably one-fourth below the true quantity, could it be ascertained. Mr. Luccock is inclined to believe that the flocks of sheep in England and Wales are not so numerous as formerly, but he says those of Ireland and Scotland are rapidly increasing. Even in England and Wales, he says, we have

WOOL.

more than three millions of acres capable of being improved, and carrying a more numerous stock. We have two millions of sheep whose fleeces are scarcely wool, and which might be brought to contribute their share to support the woollen manufacture, and to increase the wealth of the country.

It may be proper to remark, that the quantity of wool grown annually in England is more variable than is generally supposed, owing to the variable temperature of our climate. In long-continued and severe winters, the sheep not obtaining the same quantity of food, and being also rendered less vigorous by the cold, do not grow so much wool as in milder seasons. The difference between the weight of the fleeces grown in severe and in very mild seasons, may be stated at one-fifth of the whole annual clip: indeed we believe it exceeds that proportion. About the year 1700, the annual value of English wool was estimated at two millions sterling. If we suppose the average price at that time to have been eight-pence *per* pound, or eight pounds *per* pack, this will make the total weight of wool two hundred and fifty thousand packs. Indeed when

we consider the improved state of our agriculture, the great increase of our population, and of our woollen exports, we may fairly state the present weight of wool grown to be double the amount of what it was at the period referred to. In a subsequent part of this article, it will be seen that the cloth manufactures of Yorkshire, principally from English wools, have increased eight-fold in the last eighty years; and though the woollen manufactures have removed from some other situations, yet the great increase on the whole in England cannot be doubted. Since the date of Mr. Luccock's table in 1805, in consequence of the high price of long combing-wool, the growers have paid more attention to the weight of their fleeces; and many who had rendered their fleeces lighter by exchanging the Lincolnshire for the Leicester breeds of sheep, have since been reverting to the former breed, or rather to a mixed breed, endeavouring to combine the improved form of the Leicester sheep with the heavy fleece of the Lincoln. The quantity of long combing-wool grown annually is greater than it was even ten years since; the high and increasing price and demand operating naturally as a premium for its cultivation.

The wool of Scotland may, perhaps, be estimated at 70,000 packs, of which the greater part, particularly that grown in the Highlands, is of the very coarsest kind. Of the quantity of wool grown in Ireland, we can form no correct estimate, but it cannot be great. From the returns at the Custom-house, it appears that the quantity of wool imported from Ireland and the Isle of Man in 1816 amounted to about 2600 packs; whilst the value of woollens imported from England was upwards of 500,000*l.* sterling. The woollen and worsted manufactures in Ireland are no where on an extensive scale; perhaps 60,000 packs are the full amount of the wool annually shorn in Ireland: this was the amount stated about a century since.

The quantity of wool imported into England may be seen from the following return at the Custom-house for the year 1817, amounting to about thirty thousand packs. The qualities we have annexed in the last column.

An Account of the Quantity of Sheep and Lamb's Wool imported into Great Britain, in the Year ending 5th January 1817; distinguishing the Countries from whence imported.

The whole of the imported wool, with scarcely an exception, is worked on the card, none of it being suited for the comb. The coarser kinds are principally employed for carpets, &c.; and the fine from Spain, Germany, Portugal, and France, supply our manufactures of superfine broad cloths, cassimeres, &c. So large a portion being of the finer kinds, the total value cannot be less than one million and a half pounds sterling.

Wool of New Holland.—The annual value and amount of the fine wool imported into England for our own manufactures being so great, we must surely applaud the meritorious exertions of those who attempt to supply the demand with the produce of our own country, or of our dependent colonies, and more particularly if they can raise this supply from parts where no wool was before grown. In this view, it cannot fail to be highly interesting to learn, that the exertions of one enlightened agriculturist have been eminently successful in spreading over an immense region dependent on England the very finest-woolled sheep, where the soil had never before yielded any produce serviceable to civilized man.

John Macarthur, esq. descended from an ancient family in Argyleshire, captain in a regiment then commanded by general Grose, went to New Holland in 1789. Fortunately for the future prosperity of the colony, his active spirit of inquiry and enterprise led him to direct his attention to the natural advantages which the soil and climate presented to the agriculturist, and having by purchase and grants obtained a considerable tract of country, he quitted the service in 1793, and commenced his farming operations. His stock at first consisted only of a few oxen and thirty Bengal ewes, growing a coarse kind of wool or hair. About the year 1795, he obtained from captain Kent, of the Royal Navy, one Merino ram and two ewes, purchased from the Dutch governor of the Cape of Good Hope. With these he began to cross his coarse-haired sheep, and to select the finest-woolled progeny to breed from. Having occasion to return to England in 1802, he brought over specimens of his wool, which were shewn to a body of the clothiers from the west of England, then in London on public business, who were so sensible of the advantages which might result from encouraging the growth of fine wool in the colony, that they presented a petition to the privy council, by whom Mr. Macarthur was examined. His plans being approved, the privy council recommended the secretary of state for the colonies to give him an additional grant of land, in a tract of country, from its fertility, called the cow-pastures, forming part of Camden county. On his return he took with him three Merino rams and two ewes, purchased from his majesty's flocks; and thus encouraged, he proceeded with rapid steps in the increase and improvement of his flocks, the climate being every way suited to secure the healthy condition of the sheep, and preserve the fineness of the wool.

The numbers increase four-fold every five years, so that his flocks already amounted to about four thousand sheep and lambs, including the fine and mixed breeds, when the unfortunate disputes with governor Blight, and the subsequent arrest of the latter, obliged Mr. Macarthur once more to return to England, and in some degree interrupted the progress of improvement. In 1817 his flocks had increased to about seven thousand, and the wool which has been sent to this country at different times, is become an important source of profit, the better sort being equal to the best Merino piles from Spain or Saxony. What we have seen more nearly resembles the latter, and were they both in the same state of cleanness, the most experienced eye could not discern any difference between them in fineness of the hair, length of staple, soundness, colour, or other properties.

The wool has been hitherto washed on the sheep's back in the English method, by which it is not rendered so clean as by the Spanish or German mode; but making allowance for the additional waste, its value is equal to that of the very best Merino wool imported from any part of Europe.

The quantity imported this year is about eighteen thousand pounds weight, and a farther arrival is expected. The laudable example of Mr. Macarthur has been followed by other persons in the colony, and the total amount of wool sent from thence this year is about fifty thousand pounds weight; and such is the spirit of agricultural improvement, that at the annual sales of sheep established by Mr. Macarthur, rams and ewes have been sold at from ten to thirty guineas each. Though the absence of Mr. Macarthur impeded the progress of improvement, yet this will be more than compensated by the valuable information he has obtained with respect to the management and improvement of his flocks, from observations made on the continent; and he has further benefited the colony by taking back with him a selection of olive-trees, vines, and oranges. The dryness and mildness of the climate of New Holland, and the almost total absence of briars and underwood, are extremely favourable to sheep. His stock is divided into flocks of about four hundred, with shepherds and Spanish dogs to each. Under these propitious circumstances, and as the flocks double in number every thirty months, we may anticipate, that in the course of twenty or twenty-five years, the importation of fine wool from this colony will be fully equal to the total amount at present imported into England from all the different countries of Europe. It might repay the exertions of this enlightened agriculturist, and of the British government, could they procure from India the animals, whether sheep or goats, which yield the peculiarly soft wool for shawls. This would be a most valuable article, and is much wanted by our manufacturers.

There can scarcely be a doubt, that under the favourable climate of the British settlements in New Holland, all the Asiatic wool-bearing animals, particularly those of Cashmere and Thibet, might be introduced with every prospect of success. The coarse wool grown in the colony is chiefly manufactured in the country for domestic use. It is estimated that there are at present sixty thousand sheep in the colony, and a little perseverance and attention would suffice to change the coarse-woolled breeds into finer ones; a change which is at present rapidly taking place, and deserves the greatest encouragement, as wool is the only article of produce which the colonists have at present to export in exchange for British manufactured goods.

The Improvement of Wool depends primarily on attention to the breed of sheep, but there are various circumstances of soil, climate, and food, which are important to be regarded. The experiments that have been made in various parts of Europe within the last half century, have sufficiently removed the prejudice that long prevailed, respecting the impossibility of growing the finest clothing-wool in almost every part of the globe where sheep will subsist and thrive. It is different with the long combing-wools, to grow which in perfection, luxuriant pastures seem absolutely requisite, and these cannot be obtained under a parching sun, nor could the animal subsist in tropical climates, covered with such a load of wool as is grown on our sheep in Lincolnshire. Under such circumstances, an entire change seems to take place in the animal system; the long-woolled sheep become diseased and feverish, and only recover by casting the fleece, which is replaced by a coat of short hair. The rich pasture in England, and the opposite coasts of Flanders, seem more favourable to the growth of heavy combing

fleeces, than any other country in the known world; and the Leicestershire and Lincolnshire sheep seem every way well suited to these pastures, and the prices of the wool obtained at present are sufficient to secure attention to its cultivation. At one period, indeed, during the American revolution, the price of long combing-wool not being more than about three-pence *per* pound, the growers turned their attention principally to the improvement of the carcase, and neglected the weight of the fleece. At present the price is about eighteen-pence, and the average weight being about eight pounds, the wool forms an important object, and the growers are endeavouring to increase the weight of their fleeces. For the common purposes of the worsted manufactures, this wool is so well suited as to leave nothing further to be desired; and it is this kind which foreign manufacturers are so desirous to obtain from us. In many situations, however, where heavy long-woolled sheep are introduced, and where the soil is not sufficiently rich to grow it in perfection, it would be possible to grow a fleece weighing five or six pounds of very fine combing-wool, by crossing the long-woolled ewes with the Anglo-Merino rams. The increasing demand for finer goods, and the great improvement made in the spinning of combing-wool by machinery, make such a change desirable where the pastures are not sufficiently rich to bear the heavy long-woolled breeds of Leicester and Lincoln.

In many cold and exposed situations it would be desirable to provide better shelter for the flocks; and the practice of *grazing*, hereafter described, might be introduced with great advantage, and would tend to preserve the sheep and improve the quality of the wool.

The experiments made on the fine-woolled sheep on a large scale in different parts of Europe, prove that the peculiarities of food and climate have comparatively small influence on the quality of clothing-wool, and that it may be grown equally fine in situations where the sheep are confined and kept on dry meat a great part of the year, as in Saxony, Sweden, and Denmark. It may also be grown in the richest pastures, provided the pastures be over-stocked, to keep the herbage bare. There cannot, however, be a doubt, that a dry light soil, particularly in the moist climate of England, is most favourable to the health of the sheep, and to the quality of the wool.

The experiments that have been made in England on the Merino sheep have not been so successful as in other countries, principally arising from two causes.

In the first place, the demand for meat in England will always make the wool but a secondary object with the grazier, and no cross of the Merino sheep with the English has yet produced a race that equal in symmetry of form the South Down sheep, or that will produce the same quantity of meat to the butcher in the same space of time, and with the same food. In the second place, the mode of washing the Merino and Anglo-Merino wool in England will, so long as it is practised, prevent the wool from obtaining its proper value in the market. From the great quantity of natural yolk or grease in the Merino fleece, it is impossible to wash the wool on the sheep's back by mere immersion in water. In Spain no attempts are made to wash the wool upon the sheep's back, but all the fleeces of a pile are regularly sorted, and the different sorts scoured and dried before the wool is packed. But where the quantity of wool which any one grower possesses is small, as in England, it would not answer to send for wool-sorters from a distance; and to wash the wool before it is sorted, would so intermingle the fine with the coarse locks, as to render the regular sorting extremely difficult and expensive. In Saxony

Saxony and Sweden the wool is washed on the sheep's backs. The following account of the process is thus described by baron Schulz. The sheep are first washed with one part clear ley, and two parts lukewarm water, and then in another tub with less ley in the water; after which the sheep are washed, laying them always on their backs, with their heads up, in a tub with clean water; and lastly, there is poured on the sheep, when standing on the ground, a sufficient quantity of water, which is as much as possible squeezed out of the wool. The sheep are afterwards driven into an unpaftured meadow adjoining, and remain there, to prevent their soiling themselves in the sheep-house. They remain there a day and a night, or longer, till the wool be dry, which in fine weather will be in three days. Some persons wash their sheep twice, but the wool becomes harder in consequence of it, and has a greyer appearance.

The great quantity of greafe which the finest Spanish wool contains at the first washing mixes with the ley-water, and makes it quite soapy; but this greafe is wanting in the second washing, so that the water is not in the least softened. Some mode of washing like the above must be introduced in England, before the manufacturer will encourage the Anglo-Merino wool; for after his purchase, when he thinks he has obtained sufficient allowance in the price to cover the waste, he is generally much disappointed in finding the loss in the manufacture so greatly to exceed his expectation, and he is deterred from making a second trial.

In the northern counties of England, and in Scotland, a practice has long prevailed of greasing the sheep with a mixture of tar and butter, to preserve the animal from the effects of moisture, and the inclemency of the weather in hilly and exposed situations. This practice seems at present peculiar to Britain, but the ancients evidently made use of mixtures of the dregs of olive wax, tar, wine, and other ingredients, to protect the skin of sheep after shearing, and to soften and improve the wool. Such was the practice of the Italian shepherds, as described by Virgil:

“ Aut tonsum tristi contingunt corpus amurca,
Et spumas miscent argenti vivaque sulfura,
Idæalque pices et pingues unguine ceras
Scyllamque helleborosque graves nigrumque bitumen.”
Georg. lib. iii.

That this practice was extremely beneficial in warm climates, by protecting the skin of the sheep from insects after shearing, and by keeping the wool in a soft state, cannot be doubted.

The practice of greasing the sheep in Scotland, and the northern counties of England, with a mixture of tar and butter, seems to have been introduced merely to preserve the sheep, and was generally supposed to be injurious to the wool. Indeed the great proportion of tar, too frequently employed, gave some ground for entertaining this opinion; and the breed of sheep, on which this mixture was most generally applied, is naturally the worst which exists in Britain for the production of wool, the fleeces more nearly resembling coarse hair than wool; but Mr. Bakewell, in his Treatise on Wool, observes, that “in Northumberland, where the fine-wooled sheep have received the benefit of greasing with a mixture in which the proportion of tar was merely sufficient to give it due tenacity, the wool is greatly improved by the process, but the ignorance or selfishness of the wool-buyers for a long time prevented the acknowledgment of the fact.” Many were afraid to purchase the wool on account of its dirty appearance, but its value is now better understood in the Yorkshire markets, and it is purchased by the manufacturers of coloured cloth in preference to the ungreased wool

of the same degree of fineness. The same preference is also given to the cloths in the halls, where they are fold in an undressed state. When these cloths are finished, their superiority is more apparent, possessing a degree of softness far beyond the ungreased wool. These wools appear to improve in every process of the manufacture, and yield a cloth of greater value by twenty or thirty *per cent.* than the ungreased hard wools, though the latter may be equally fine.

But even in Northumberland, where the wool is so greatly improved by the practice, its good effects in this respect are not sufficiently known, and the operation is delayed till the approach of winter. By this delay, the upper part of the staple which is first grown, is deprived of the advantage of being kept in a moist soft state during the summer heat. When the operation has taken place, a perceptible improvement may be observed in the wool which is afterwards grown. The line of distinction is clearly marked by the stain which the unguent leaves in the staple, the bottom part of which, where it is applied, is finer and softer than the upper part which was grown before its application. This difference is so great, that a careful examination of the fine-greased wools of Northumberland might alone be sufficient to demonstrate the advantage of the practice, and the inconvenience of delaying the operation to the end of the year. To derive the most advantage from the ointment both to the wool and the sheep, it should be applied immediately after shearing, and again at the approach of winter. By the first greasing, the wool will be kept soft and moist during the sultry heats of July and August, and the top of the staple would not become harsh and discoloured, which is frequently the case with English wool. One acknowledged advantage of greasing immediately after shearing should not be overlooked; it destroys the sheep-tick, and has a tendency to prevent cutaneous distempers, and to protect the skin from the bite of the fly. The manner of preparing the ointment in Northumberland is as follows:—From sixteen to twenty pounds of butter are placed over a gentle fire, and melted; a gallon of tar is then added, and the mixture stirred with a stick until the tar and butter are well combined, and form a soft tenacious ointment. Some skill is required in its application, the want of which has prevented the practice from prevailing more generally. If the ointment be rubbed on the wool, it collects on the top of the staple, where it detains the loose soil, and becomes hard, and is injurious to the wool. The proper method is to divide the staples or locks with one hand, and apply the ointment with the finger immediately upon the skin; it is thus kept constantly soft by the warmth of the animal, and is equally diffused through the fleece. Attention to this circumstance is of the greatest importance to the success of the practice. The quantity laid on each animal varies in different districts. In the lighter mode of greasing, one gallon of tar and twenty pounds of butter will be sufficient for fifty sheep. In Scotland, where greasing is applied merely to preserve the animal against the inclemency of the climate, a much larger portion of tar is used: this would be very injurious to the wool, were it of any other than the very coarsest kind.

Could a cheap substitute for tar be found, which would possess equal tenacity, the ointment might be applied with great advantage to all our native breeds of English sheep, both for the preservation of the animal and the improvement of the wool. Mr. Bakewell states, that long combing-wools, which have been greased in this manner, produce a softer and superior yarn to any ever made from wool of the native English breeds which have not undergone the process.

cefs. On all chalk and light calcareous foils, the wool is always much harfter than wools of the fame degree of fineness grown on argillaceous or filiceous foils; and this arises from the calcareous earth penetrating the fleece, and absorbing the natural grease, and thus rendering the fibres hard and elastic. These foils cover a large portion of the south-eastern counties of England, and of some of the midland counties; and it is well known to cloth manufacturers that the wool from these districts do not work so well, nor make so soft a cloth, as wool on siliceous or argillaceous foils. Nor will this wool felt in the fulling-mill like the softer wools. The practice of greasing would be of undoubted advantage in calcareous districts, applying the ointment more sparingly than in the northern counties. Perhaps twenty-five pounds of butter, and one of tar, or two of bees'-wax, might be sufficient for one hundred South-Down sheep; and if the mixture were applied once after shearing, and again in October, the expence would be abundantly compensated by the improved condition both of the sheep and wool. The softness of wool appears to be essentially connected with the property of felting, and depends partly on the structure of the surface of the fibre, and partly on its possessing but a moderate degree of elasticity. The process of felting is best illustrated in the hat manufacture, where the fibres of wool or fur are brought into contact by pressure and warmth, and form a compact substance without the aid of spinning and weaving. In some parts of Tartary, coarse cloth for tents is manufactured by spreading the wool on the ground, and pressing it in warm water with the feet; this was probably the first mode of making cloth. All good woollen cloth is still woven comparatively loose, and is made firm and close in the fulling-mill. The fibres of wool or fur have a tendency to move more easily in one direction when pressed, than in the opposite direction. This motion has been compared to that of an ear of barley placed under the coat-sleeve, with the points of the beards downwards; by the action of the arm the ear is moved in a retrograde direction, until it has advanced from the wrist to the shoulder. When we draw a hair of wool or fur through the fingers in a direction from the points to the root, we can feel a sensible degree of roughness, which is not felt if the hair be drawn from the root to the point. Hence we may suppose, that the surface is covered with a number of points or rings, which are too minute to be observed by the microscope, except in some kinds of fur, as in that from the South-sea seal, in which, with a powerful microscope, we have seen the surface covered with distinct leaves or points, shaped like those of the artichoke. We have a striking illustration of this tendency of the fibre to move in one direction in that particular process of hat-making, where it is intended to cover the felt or substance of the hat with fur of a superior kind. The felt on which this fur is to be laid being finished, the hair of the beaver is uniformly spread upon the surface, and being covered with a cloth, it is pressed and agitated by the hand for a certain time. The fibres of beaver-hair introduce themselves by their roots into the felt, and proceed to a certain depth, and become firmly fixed in it. If the pressure were continued for a longer time, the hairs would pass entirely through the felt, going out at the under surface, as each hair follows the direction it acquired at the beginning of the process.

As the felting property, therefore, seems to depend on the minute structure of the surface of the fibre, it is easy to conceive how this may be injured by a dry calcareous soil, and how this property is best preserved in those furs

which are grown under a covering of coarse hair, and protected from external injury. The process of greasing is in some respects a substitute for such a covering, and not only defends the surface, but prevents the fibre from becoming dry, harsh, and elastic. The ancient Greeks and Romans were in the practice of covering their soft-woolled sheep, called *molles oves*, with skins: this has been supposed to have been intended merely as a protection from briars and underwood; but we have no doubt that wool so covered would be much softer than wool exposed to the action of light, and of the soil. That the rays of the summer sun have a tendency to make wool both coarser and harfter, may be seen in the effect produced on sheep that are exposed to it without shelter immediately after shearing. The top point of the staple which was grown at that time is almost always coarser and harder than the bottom of the staple which has been grown under the cover of the upper part of the fleece, and consequently more protected from light. An analogous effect is produced on the skins of horses kept in coal-mines, which become sleek and soft. These facts may suggest to wool-growers desirous of improving their wool, the advantage of providing shade for their flocks during the sultry heats of summer. The natural instincts of sheep might teach them the impropriety, not to speak of the cruelty, of keeping their sheep in summer inclosed in pens, and unsheltered, upon a dry soil, where the animals are almost roasted alive; a practice not less injurious to the health of sheep than to all the best qualities of the wool. Next to a regular supply of food, protection from the effects of heat and wet are objects of the first importance in the management of sheep; and it may be stated as an undoubted truth, that whatever contributes to the comfort of the animal, will enable it to fatten with a smaller quantity of food, will tend to preserve it in a healthy state, and will also increase the quantity and improve the quality of the wool.

Wool, Chemical Examination of. The chemical properties of wool are very similar to those of hair, and as we omitted to speak of these in their proper place, we shall introduce them here.

From the experiments of Achard and Hatchett, it appears that hair contains gelatine, to which it owes its suppleness and toughness. When hair is boiled in water, this principle is separated, and the hair becomes much more brittle than before. Indeed, if the process be continued long enough, the hair crumbles to pieces between the fingers. The portion insoluble in water possesses, according to Mr. Hatchett, the properties of coagulated albumen.

Mr. Hatchett has concluded, from his experiments, that the hair which loses its curl in moist weather, and which is softest and most flexible, is that which yields its gelatine most readily; whereas strong and elastic hair yields it with the greatest difficulty, and in the smallest proportion. This conclusion has been confirmed by a very considerable hair merchant in London, who assured him that the first kind of hair was much more injured by boiling than the second.

Vauquelin has published a curious set of experiments on human hair of different colours. He found it completely soluble in a Papin's digester. During this process, sulphuretted hydrogen was evolved. The solution thus obtained contains a kind of bituminous oil, which is deposited very slowly. This oil was black when the hair was black, but yellowish-red when red hair was the subject of experiment. When this oil was removed, nut-galls and chlorine produced copious precipitates. Silver was blackened, and acetate of lead precipitated brown. When concentrated by evaporation, it did not concrete into a jelly.

WOOL.

Water containing only four *per cent.* of potash dissolves hair, while hydro-sulphuret of ammonia is evolved. If the hair be black, a thick dark-coloured oil, with some sulphur and iron, remain undissolved. If the hair be red, this oil is yellowish. Acids throw down from this solution a precipitate, soluble in excess of acid.

Sulphuric and muriatic acids become red when first poured on hair, and gradually dissolve it. Nitric acid turns hair yellow, and dissolves it, while an oil separates, varying in colour, as before-mentioned, according to the colour of the hair employed. The solution contains a great deal of oxalic acid, besides bitter principle, iron, and sulphuric acid. Chlorine reduces it to a substance of the consistence of turpentine, partly soluble in alcohol.

Alcohol, digested on black hair, extracts from it two kinds of oil. The first, which is white, subsides in white shining scales as the liquor cools; the second is obtained by evaporating the alcohol. It has a greyish-green colour, and at last becomes solid. From red hair alcohol also extracts two oils, one white, as above, the other red as blood. After this latter has been extracted, the hair becomes chestnut. Hence its red colour appears to depend upon this oil.

Hair on incineration yields iron and manganese, sulphate and carbonate of lime, muriate of soda, and a considerable proportion of silica. The ashes of red hair contain less iron and manganese. Those of white hair still less; but in those we find magnesia, which is wanting in the ashes of other hair. The ashes of hair do not exceed .015 of the hair.

Hence, according to this analysis, hair consists of

1. Animal matters constituting the greatest part.
2. A white solid oil, small in quantity.
3. A greyish-green oil, more abundant.
4. Iron, state unknown.
5. Oxyd of manganese.
6. Phosphate of lime.
7. Carbonate of lime, very scanty.
8. Silica.
9. Sulphur.

Vauquelin infers from these experiments, that hair depends for its colour upon a kind of oil, which varies according to the colour of the hair in which it is found. He also supposes, that sulphuret of iron contributes to the colour of black hair. The sudden change of colour in hair from grief, he thinks, is owing to the evolution of an acid. Bichat, however, attributes this change, perhaps with greater probability, to the absorption of the colouring principle. To whatever cause it be owing, the fact appears undoubted; and it shews a closer connection between the living powers and the hair, than many physiologists are inclined to admit.

Wool appears, according to the experiments of Berthollet, to coincide almost exactly in its chemical properties with those of hair above-mentioned. When growing on the back of the animal, it is enveloped in a greasy matter, called the *yolk*, and which appears to be a kind of soap; or, more properly speaking, according to the experiments of Vauquelin, who has examined it, of

1. A soap of potash.
2. Carbonate of potash.
3. A little acetate of potash.
4. Lime.
5. A little muriate of potash.
6. An animal matter.

This substance appears to have the property of protecting the animal from insects to a certain degree, and of preserving

the softness of the wool, which are perhaps its chief uses. It is removed from the wool before it is manufactured, by the process termed *scouring*. The affinity of the animal matter of wool for all colouring principles is very great, and in general far exceeds that of the different vegetable fibres, as cotton, flax, &c. for such principles. There is one kind of coarse wool, however, which, according to Dr. Bancroft, does not possess this property, and receives colours with great difficulty. See *DYEING*, and the preceding article.

WOOL, Laws relating to. The jealousy entertained on the subject of our wools, may be learnt from the legal restriction which has been made in relation thereto; as also with the view that as much employment as is possible may be found for the labouring classes. This is effected by the prohibition of the exportation of wool in an unmanufactured state, as will be seen below. It must be obvious, however, that it would be to little purpose to be thus strict respecting the article itself, if that which produced it was not equally guarded; therefore as early as 13 & 14 Ch. II. c. 18. it was made felony to export sheep from England or Ireland, or even to Scotland: now however the penalty is forfeiture of every ram, sheep, or lamb, and the vessel in which such is shipped with intent to exportation from Great Britain and the islands belonging thereto; and offenders are to forfeit 3*l.* for every sheep, &c. so shipped, and to suffer three months solitary imprisonment, and till the forfeiture be paid, but not to exceed twelve months; and for any second offence 5*l.* for each ram, &c. and six months imprisonment, and till the fine is paid, but not to exceed two years. 28 Geo. III. c. 38. § 2.

By the 9th and 37th sections, no wool, woolfells, mortlings, yarn, or worsted made of wool, woolstocks, coverings, cruels, waddings, or other manufactures, or pretended manufactures slightly wrought up so that it may be reduced to wool again, or mattresses, or beds stuffed with wool combed or fit for combing or carding, may be shipped or exported, or carried or moved for that purpose, from Great Britain, or Guernsey, Jersey, Alderney, Sark, or Man, to any foreign place, on forfeiture of the wool, with the carriage, ship, or cattle on which it is laden or removed; but 300 sheep may be sent annually from Liverpool or Whitehaven to the Isle of Man (51 Geo. III. c. 50.); and the person offending to forfeit 3*s.* for every pound weight, or 50*l.* in the whole, and to be imprisoned three months, and till the penalty is paid, but not to exceed six months; but for a second offence he is to forfeit the like sums, and to be imprisoned for six months, and till such fine be paid, not exceeding two years; but this is not to extend to lambskins dressed for furs and linings.

And persons qualified by the governors of the following islands may export the respective qualities set against them from Southampton to those places in every year:

	Tods.
To Jersey - -	4000
To Guernsey - -	2000
To Alderney - -	400
To Sark - - -	200

28 Geo. III. c. 38. § 16, 17. And 20,000 pounds weight of worsted and woollen yarn may be exported annually from London to Lower Canada, by permission of his majesty in council. 47 Geo. III. c. 9. 52 Geo. III. c. 55.

By the 48 Geo. III. c. 44. wool may be shipped in England for exportation to Ireland, on being duly entered and bond given for its true exportation there; and upon obtaining a licence under the hands of the commissioners of the customs to allow it.

No wool shipped to be sent coastwise from one part of Great Britain to another, until due notice be given and bond entered into, and a licence obtained under the hand of three commissioners of the customs. Penalty, forfeiture. 28 Geo. III. c. 38. § 34. And wool must also be shipped coastwise in British ship, British owned and manned, the owner of which does not reside out of Great Britain. § 19. and 12 Car. II. c. 18. Formerly there were penalties and forfeitures for keeping or removing wool in Kent and Sussex within certain distances of the sea (ten and fifteen miles), without entry and bond, and procuring certificates or permits, and also for removing wool within five miles of the sea-coast of Great Britain before sun-rising and after sun-set; but by the 54 Geo. III. c. 78. all the regulations formerly required *antecedent to the removal of wool on land throughout England* are repealed.

Wool to be packed in packs, or trusses of leather, or canvas, called 'Pack-cloths,' or in linen or woollen, and to be marked 'Wool,' in letters three inches long, on forfeiture of the wool, and 1s. per pound. 28 Geo. III. c. 38. § 28.

Persons packing wool, &c. into boxes, barrels, casks, or chests, and other than as above, or pressing or steaming the same, to forfeit the goods, and 3s. per pound. *Ibid.* § 30, 31.

Infurances for the conveyance of wool contrary to this act void, and the parties may be punished. § 45, 46, 47, 48.

King's ships empowered and required to search ships for wool shipped without licence. § 49, 50, 51.

No person can seize wool unlawfully removing but officers of customs, excise, and salt-duties, or persons accompanied by a constable (§ 52.); and persons neglecting their duty to forfeit 20l., and making collusive seizures or agreements to be subject to like penalties as exporters. (§ 53, 55.) Hindering, obstructing, or beating officers, subjects offenders to transportation; and bribery of them, whether accepted or not, to the penalty of 300l. § 56, 57.

If any question arises upon the growth of the wool, the *onus probandi* is to lie upon the owners. § 60.

Informations may be laid in any court of record, and penalties, &c. under 200l. may be determined before two justices of the peace; and justices at quarter-sessions may direct ships, goods, wool, &c. to be sold. § 62, 63.

Prosecutions to be commenced within three years. § 77.

Wool the growth of Ireland may be exported to England, and no where else. 1 W. & M. c. 32. 7 & 8 W. III. c. 28. 10 & 11 W. III. c. 10. 26 Geo. III. c. 11.

And the Admiralty is to appoint three ships of the sixth rate, and eight or more armed sloops, to prevent the exportation of wool from Ireland to foreign ports. 5 Geo. II. c. 21.

Wool the produce of any of the colonies, &c. in America, or countries on the continent of America, subject to any foreign European states, imported into certain British West India islands, may be imported into Great Britain under the regulations of the 12 Car. II. c. 18.

Those places are, Jamaica, Granada, Dominica, Antigua, Trinidad, Tobago, New Providence, Crooked island, St. Vincent, Bermuda, Caicos, Tortola, Curacoa, and the Bahamas. 27 Geo. III. c. 27. 45 Geo. III. c. 57. 47 Geo. III. sess. 2. c. 34.

British hare or coney wool may not be exported, (except to Ireland, 39 & 40 Geo. III. c. 67.) on penalty of forfeiture. The owner or shipper to pay 100l., and the master of the ship 40l. 24 Geo. III. c. 21.

Wool, *Cheese made under*, in *Rural Economy*, a term

applied to that sort of high-tasted ewe cheese which is made before the sheep are shorn. See CHEESE.

Wool, *Pack of*, a quantity of wool packed up closely together in a large bag of the sack-cloth kind, which in London is constituted of two hundred and forty pounds. See WOOL.

Wool, *Pocket of*. See POCKET.

Wool, *Sarplar of*. See SARPLAR.

Wool-*Stapler*, a person who staples and deals in wool. See WOOL.

Wool-*Stapling*. See STAPLING of Wool.

Wool-Balls, in *Natural History*, masses of wool compacted into firm and hard balls, and found in the stomachs of sheep, as the hair-balls are in oxen and other animals.

These are doubtless formed in the same manner as those hair-balls of the outer covering of the animal; but they are much more uncommon; they are found in numbers, three, four, or five, in the stomach of the same animal. Their outside has commonly much the same appearance of a puff-ball, and is usually either in part or wholly covered with a very thin and soft blackish smooth skin; the inner substance is entirely wool, but that wrought together as closely as the latter does his furs in the making of them into hats.

They are usually soft, smooth, and somewhat elastic, of a pale buff-colour, very light, and of irregular figures rather cubic than globular, and seldom of any great size, an inch in diameter being their common standard. Moreton's Northampt. p. 451. See BALLS.

WOOLASSEY, in *Geography*, a town of Bengal; 42 miles N.E. of Calcutta.

WOOLDALE, a township of England, in the West Riding of Yorkshire, near Wakefield.

WOOLDAW, a town of Bengal; 40 miles W. of Nagore.

WOOLDERS, *Single and Double-Handed*, in *Ship-Building*, are sticks about three feet long, and four inches in circumference, with straps of rope-yarn made fast, to fix on the rope in making, and assist the men at the hooks in closing the rope.

WOOLDING, is winding several close turns of rope in a tight manner round the masts and yards, that are made of several united pieces, to strengthen and confine the same together. In making new masts and yards, this method is discontinued, and iron hoops used in lieu.

Woolding is also the rope employed in this service.

WOOL-DRIVERS, are those who buy wool of the sheep-owners in the country, and carry it on horseback to the clothiers, or market-towns, to sell it again.

WOOLER, anciently WILLOVE, in *Geography*, a market-town, and parish in the ward of Coquet-dale, and county of Northumberland, England. The former is situated near the Cheviot-hills, 17 miles S. from Berwick-upon-Tweed, 46 N. by W. from Newcastle, and 320 in the same direction from London. In 1811 the houses in the parish were 284, inhabited by 1704 persons. A market is held on Thursday, and fairs on the 4th of May and 17th of October. Wooler was a barony, and consisted of several manors in the time of Henry I., who conferred it on Robert de Muscamp, whose successor Robert, in the reign of Henry III., was the most powerful baron in the north of England: it now belongs to the earl of Tankerville. The church was rebuilt in 1765, and the town contains some meeting-houses for dissenters. Situated near the confines between the kingdoms

WOOLLEN MANUFACTURE.

doms of England and Scotland, the environs of Wooler present many intrenchments, cairns, and other memorials of the sanguinary conflicts which in former times occurred between the rival nations on the borders. About ten miles N. from the town, on the road to Scotland, is the celebrated Flodden-field, where the Scotch, in 1513, received a signal defeat, and James IV. was slain.—*Beauties of England, Northumberland*, by the Rev. J. Hodgson, 8vo. 1812.

WOOLHASA, a town of Algiers; 6 miles N.W. of Tackumbreet.

WOOLLEN MANUFACTURE, *Progress of the*. The origin of the woollen manufacture, like that of many other useful arts, is not precisely known. At a very early period, domestic sheep were extensively spread over Western Asia. The introduction of sheep into Europe is not recorded by ancient writers, unless we suppose the expedition of the Argonauts to Colchis refers to this event. Sheep were probably first domesticated for their milk, and afterwards for their skins, which must have been the first dress of pastoral nations. Sheep and goats, in the early ages of society, were nearly of equal value. The Greeks, who ostentatiously refer all useful discoveries to their own country, and rank their inventors among the gods, have ascribed to Minerva the invention of spinning and weaving. These arts appear, however, to have been first practised, at a very early period, in Egypt, and applied to the spinning and weaving of flax. At what time they were first applied to wool is unknown. Though Pliny informs us, that Nicias of Megara discovered the art of fulling cloth, the property which wool possessed of felting was known in the East at a much earlier period, and probably gave rise to the first manufacture of woollen goods which were not woven, but felted like the substance of hats.

On this subject, Mr. Luccock, in his *Treatise on Wool*, judiciously remarks, " whilst the skins of sheep dressed with their wool on served as clothing, it is obvious that only one useful fleece could be obtained from one animal, and as the fleece is generally cast, or falls off once a year, this produce must have been wasted. In a very early period, however, the property which wool possesses of felting was discovered, or, in other words, it was found that by pressure and moisture the fibres of wool might be made to adhere together, and produce a compact pliable substance, quite as durable and more convenient than the skins formerly used. This appears to have been the first effort to produce a woollen manufacture." It is probable the felting property was discovered by accident, as some fleeces will felt upon the sheep's backs; among farmers, these are called cotted fleeces. When the application of this discovery was first made, the knowledge of the art was soon widely spread. The tents of the Arabs and Tartars are, at the present day, all made of felt from the wool of sheep, mingled with the hair of goats, camels, and other quadrupeds, and may be considered as remains of the original art of cloth-making.

The art of spinning and weaving threads made from wool was, in all probability, derived from the East; they are alluded to by Moses as existing nearly fifteen hundred years before the Christian era, and it appears that the early patriarchs had numerous flocks of sheep.

The greater part of these sheep, we are informed, were, at first, either dark-coloured or spotted; hence we may infer that the art of dyeing wool was then unknown. When the selection and cultivation of white wool gave to woollen cloth the property of receiving the tints of the dyer, the value and use of wool must have greatly increased, owing to the great estimation in which richly-coloured garments are held by people advancing to a state of civilization.

Thus, in addition to the superior pliability and comfort of woollen cloth, compared with skins or felts, the taste for it must have been widely spread by the art of dyeing. It had also the great recommendation to its general adoption, that it could be fabricated with ease in every family. The machinery required for the purpose was extremely simple. The distaff and the loom, says Mr. Luccock, were little more in the hands of the first manufacturers, than the spade in those of the husbandman. Spinning and weaving, as we have already observed, were in use at least fifteen hundred years before the Christian era; but the manner in which they were performed is not related until about three centuries afterwards. Then the loom consisted of a frame of wood, in some respect different from the modern one, but well adapted to the same purposes.

The alterations which have been made in it consist, perhaps, more in the position of the beam, and the mode of opening the web for the passage of the shuttle, than in any other circumstance. Nor was the earliest mode of spinning less perfect, than that which was practised in the most celebrated manufacturing countries for many ages afterwards. It was performed by means of a rod or staff, about which the wool to be spun was carefully wrapt, and held in the left-hand, while a rough kind of spindle, quickly twirled betwixt the right-hand and the thigh, was suffered to continue its motion when suspended by the thread which the artist gradually lengthened with his fingers. This least complex of spinning-machines is not entirely laid aside even now. A few years since it was not uncommon in the county of Norfolk, and its continuance in use through so many ages is the best proof of its excellence.

The preparing of wool for spinning was probably first effected by the fingers, and afterwards by the fuller's teazle or thistle, the *diplacus fullorum*, which with its rough and hooked points was well adapted to the purpose, and has continued in use to the present day. The card afterwards used was probably a substitute for the *carduus*, or teazle. The application of the wheel to a spindle, or the spinning-wheel, is, we believe, unnoticed in history. Whenever these inventions took place, it is probable their first introduction contributed more to increase the quantity, than improve the quality of the yarn and cloth. For a considerable period after the commencement of the woollen manufacture, the improvements made in spinning or weaving of wool were effected by the improved address and skill of the manufacturer, rather than by any alteration in his machinery, as we now see the manufacturing nations of the East execute very elaborate works with instruments of the most simple construction. In proportion as luxury and refinement increased, the demand for superior fabrics would induce the growers of wool to pay great attention to the fleece, and to select and preserve for breeding those sheep which produced the softest and finest wool; with the ancients these terms were synonymous. The produce of fine white wool from sheep is entirely the result of cultivation; it has never been grown except in countries where the woollen manufactures have flourished. The race of fine-woolled sheep has, however, been partly preserved in those countries after the destruction of their trade. The grower would also soon learn to pay particular attention to the whiteness of his fleeces, as a clear white ground is necessary for receiving the most brilliant dyes. Blue, purple, and scarlet, were the tints most admired; and though the ingredients, by means of which they were produced, are in some measure unknown, yet we have the most indubitable testimonies to their excellency, and the estimation in which they were held. To produce them in their richest
lustre,

lustre, a selection of the wool most adapted to receive them must be made, and this would operate with great precision upon the wool-sorter's attention.

While the manufacture of wool was confined to the houses of the grower, and the business of it transacted by his domestics in a secluded state, there was less room for the stimulation and exercise of invention than in after-ages, when it became the appropriate calling of one particular part of the community, and their success depended upon the opinion which others formed of the fabric. Yet in the simplest days of Greece, it was not deemed an employment unsuitable to palaces, nor did a princess degrade her dignity by superintending the labours of the loom, the distaff, and the dyeing vat.

We have little information respecting the woollen manufactures of the Greeks and Romans, as distinct from their domestic manufactures; but large establishments were necessary for the clothing of distant armies, and for foreign commerce. That the Romans had carried the manufacture of fine woollen cloth to a high degree of perfection, is proved by a variety of circumstances, and particularly by the great attention paid to the cultivation of fine-woolled sheep, and by the high prices at which the wool and sheep were sold, as appears from the writings of Pliny, Varro, and Columella. Pliny describes two kinds of sheep: the one which grew coarse long wool, and was on this account called *hirtum* or *hirsutum*, and from its hardness and ruder treatment *colonicum* or rustic; the other breed was called *molle*, from the softness of the wool, and *generosum* or noble, from its excellence; also *pellitum*, from its being clothed with skins to protect the wool. The race is sometimes also called Tarentinum, Apulum, Calabrum Atticum, and Græcum, from the neighbourhood or district in which it chiefly lived; but what is of more importance, as shewing the origin of the fine-woolled sheep of Italy, the race is called Asianum; and, according to Pliny, a similar race existed in his time at Laodicea in Syria. The description given of these sheep by Pliny agrees with the present race of Merino sheep. There is not, says Dr. Parry, throughout Europe, any breed of short-woolled sheep now existing besides the Merino, of which the males are horned and the females not.

That the Romans imported their Tarentine sheep into their western colonies, with the art of manufacturing fine cloth, we learn from Strabo and Pliny. The former writer, who flourished in the reign of Augustus, says, that in Turdetania in Portugal, then a part of Spain, "they formerly imported many garments, but now their wool was better than that of the Coraxi, and so beautiful, that a ram for the purpose of breeding was sold for a talent, and that fabrics of extraordinary thinness were made of this wool by the Saltræ." Probably this was similar to the shawl cloth of India, and woven in the same manner, as Pliny calls it *scutulatus*, a term which he applies also to the spider's-web. The little attic talent of silver is estimated to equal in value 216*l.* of English money, which shews the high estimation in which the best wool was held even in the colonies of Rome.

All ranks of people of both sexes among the Romans chiefly wore woollen garments. In the reign of Aurelian, 270 years after Christ, a pound of silk, according to Vopiscus, was equal to a pound of gold. A people so pre-eminent in wealth, and in all the refinements of art, would naturally be solicitous to attain the highest degree of excellence in the manufacture of those fabrics, which were calculated to gratify their passion for adorning their persons, and it was equally as necessary to consult their ease as

their vanity. The summer-heat of Italy was so great, that the affluent could scarcely have supported a woollen dress, had it not been made of the lightest and thinnest cloth. We find also, that during the Augustan age, and for a considerable time afterwards, it was the fashion to wear cloths which, as at present, were furnished with a raised nap or pile. Such cloths were called *pexæ*, in contradistinction to *tritæ* or thread-bare. Thus Horace:

"—— Si forte subucula pexæ
Trita sub est tunicæ —— rides."

"You laugh if you espy a thread-bare vest
Under a well-dressed tunic."

And also Martial:

"Pexatus pulchre, rides mea, Zoile trita."

The term *pexatus*, applied to cloth, leads us to suppose that the nap or pile was raised with a comb, having very fine teeth. Pliny informs us, that in his time the price of wool had never exceeded 100 sesterii the libra, or pound; now the Roman sesterius being about 8*d.* of our money, and the libra about 5245 grains, it follows that an avoirdupois pound, or 7008 grains, would have cost about 1*l.* 2*s.* of our money. From the intercourse with Persia and the East, the Romans would become acquainted with the shawl-cloths of India, and would naturally wish to imitate so beautiful and delicate a fabric. These are made from very soft fine short wool, and not from combed wool, as has been generally supposed in this country. The existence of that manufacture in Hindoostan for many ages, is a proof of the high degree of perfection to which the fabrication of woollen cloth had been carried in former times. For shawl-cloth is only woollen cloth, woven with a twill, and unmilled, but it is spun to a great degree of fineness, and from wool so peculiarly soft, that it has never been rivalled by any European nations. The perfection of the colours, and the skill displayed in the weaving, we have no reason to believe are greater now than in the time of Alexander the Great; and if these manufactures were successfully imitated by the Greeks or Romans, or even distantly approached in the manufacture of their fine cloths, we may form some idea of the perfection to which they had arrived. When in the decline of the Roman empire, their colonies were overrun by savage barbarians, all their public establishments and manufactures were destroyed, but the art of producing from the fleece a warm and substantial clothing was never entirely lost, even during the darkest days of ignorance. It began to revive, and became the separate occupation of one class of the community about the middle of the tenth century in the Low Countries, where it remained the glory of the people, and the source of their opulence, through more than four hundred years. The wool which it consumed for the first few years was the produce of their own pastures, which had but lately been reclaimed from the forest; but as the manufacture extended itself, the demands became larger, and were supplied from a greater distance. The wealth which it distributed was soon visible, and people crowded into the country, engaged in its commerce, and pushed their speculations with increasing vigour through a hundred and fifty years, when an inundation of the sea threatened to involve the art, the artist, and the country, in one general destruction. The dispersion of the people who fled from the calamity which appeared to overwhelm their hopes, instead of destroying the infant manufacture, gave it additional vigour, and was the means of establishing a connection between

WOOLLEN MANUFACTURE.

tween the Netherlands and foreign countries, which proved of the highest importance to commerce. It contributed to a much more speedy recovery of the arts connected with the woollen manufacture, from the ruin which seemed to threaten them, and gave a striking instance of their partiality for the seats where they have once flourished, under the patronage of a government liberal enough to encourage, and sufficiently powerful to protect them, even in situations attended with natural disadvantages. The influence of these manufactures upon the fleeces of the Low Countries must have been very considerable; for before the year 960 we have no reason to suppose that their quality was superior to that which we find in the neighbouring districts; yet it was not very long ere Flanders and Brabant became famous for the manufacture of fine cloths, even at a period when they imported but little foreign wool. Perhaps the fabrics might not be equal to those which we now produce from the fleeces of Spain, or even from the improved ones of our own sheep, but they were preferable to those of England and the nations of the continent, Italy and Spain excepted. It was about the year 1200 that the merchants began to import the wools of other countries, to extend their connections much more widely, and to grow by this means still more rich and powerful. The manufactures required a larger quantity of the raw material than usual, and the population of the country had reached that extent which does not admit of a great number of sheep being kept, even though the employment of the people depend upon the fleeces, and their subsistence upon the food which they furnish. We shall observe instances of a similar kind when we treat more particularly of England. The operation of these two causes was evidently sufficient to induce the manufacturer to go farther from home, and to seek the most convenient methods of supplying his looms. It might have been expected that he would have turned his attention to France and to Germany; but independent of the hostile dispositions of some of the neighbouring sovereigns, the raw material was too bulky to be conveyed at an easy expence through the bad roads of a half cultivated country; and the ships of Spain and of Britain, who found an interest in supplying the wants of the Netherlands, unladed their cargoes almost at his very door, and solicited in payment but little else than the goods which he had manufactured.

Spain was the first country on the western side of Europe, where the Tarentine breed of fine-woolled sheep were cultivated with success by the Romans. See SHEEP.

This breed, intermixed with the native flocks, gave rise to the present fine-woolled sheep of Spain; and it does not appear that this valuable race was ever greatly neglected in that country. That it abounded in sheep in what is called the middle age cannot be doubted. At the period when the Saracens extended themselves in Spain, about the eighth century, to use the quaint words of Roderic, archbishop of Toledo, "it was fruitful in corn, pleasant in fruits, delicious in fishes, favourable in milk, clamorous in hunting, and gluttonous in herds and flocks,"—*gulosæ armentis et regibus*. He wrote in A.D. 1243. In England at that time sheep were so scarce, that a fleece was estimated at two-thirds the value of the ewe which produced it, together with the lamb.

Into Spain the invaders either carried the arts of luxury, or, what is more probable, improved them by their superior industry. The revenue of one of their sovereigns in the tenth century amounted to six millions sterling; a sum, says Gibbon, which at that time probably surpassed the united revenues of the Christian monarchs. When, several centuries afterwards, the Saracens were gradually expelled by their

Christian neighbours, Spain saw nothing but the change of religion to compensate the loss of population, of agricultural and mechanical science, of industry, and wealth. On the recovery of the Seville from the Moors in 1248, not less than 16,000 looms are said to have been found in that city. Of these, the greater number was probably employed in the fabric of woollen cloths. According to Uftarix, "Theory and Practice of Commerce," the manufactures of Segovia flourished most, both in point of number and quality, and were in high esteem, being the best and finest that were known in ancient times. The temperature of the climate, and the luxurious propensities of the inhabitants, would naturally determine these fabrics to be of the lightest and softest kinds. Hence in the midst of the boasted ancient manufactures of England, we read only of two or three instances of the importation of English cloth into Spain. The Spaniards had certainly at that time their own native fleeces best adapted to their own taste and climate.

We are told by Dillon, in his "History of Peter the Cruel," that the woollen cloths of Barcelona were in high esteem in Seville in the reign of that prince, and in the preceding century. So far back as 1243, the woollen cloth of Lerida is spoken of in terms of great estimation. A few years after, Baurlas, Valis, Gerena, Perpignan, and Tortosa, were remarkable as manufacturing towns, and for the fineness of their cloths, fustians, and serges. So great was their exportation, that in 1353 there were 935 bales of cloth taken on board a ship from Barcelona to Alexandria by a Genoese privateer; and 1000 bales of cloth were taken on board three Catalonian ships in 1412, by Antonio Dorco, in the port of Callus. We are told by the same author, that, according to records still extant in Barcelona, considerable orders for wool were sent to England in 1446, in order to be manufactured there and returned to England in the form of cloth, the Spaniards themselves disdaining to wear it.

According to Lucius Marineus Siculus, who wrote in the time of the emperor Charles V., Spain was then full of herds and flocks, more especially it contained innumerable sheep; so that many shepherds, whom he knew, had flocks of 30,000 each; on which account Spain not only supplied its own people most abundantly, but also foreign nations, with the very softest wool.

This account is confirmed by what is related by Sandoval, who states, that in an insurrection in Spain in 1519, the army of insurgents, among whom were many cloth-workers, stipulated, among other points, that the cloths imported into Spain should be of the same size and goodness as those wrought there; and that the merchants and clothiers might have leave to seize, in order to work up, half the wools sold for exportation, paying the owners the price at which they had been bought. Hence we learn the superiority of Spanish cloth, and the great sale of Spanish wool to foreign countries at that time.

Damianus a Goes, who was page to Emanuel, king of Portugal, in 1516, has written a short account of the memorable things of Spain, which he dates at Louvain in the year 1541. In this work he says, that there are annually exported from Spain to Bruges 40,000 sacks of wool, each selling at the lowest for twenty gold ducats.

Now from an authentic acquittance, preserved in the Fœdera, from queen Elizabeth to Cosmo de Medici, for a sum borrowed by him of Henry VIII., we find that the gold ducat or florin was in 1545 equal to five shillings of our money. In this year, the 36th of Henry VIII., the base coinages began; but as queen Elizabeth seems to have continued receiving the instalments of the Florentine debt

for several years at the same rate, when the shilling was of something more than the present value, we think it probable that the rate was fixed at the beginning of the year 1545, when the shilling was at 1s. 1 $\frac{3}{4}$ d. of our present coin. This wool was, therefore, worth at least 5*l.* 14*s.* 7*d.* the sack of 181 $\frac{1}{2}$ lbs., and 11*l.* 9*s.* 2*d.* the sack of 364 lbs.

In 1560, in the time of Guicciardini, Spanish wool in the Netherlands was at a somewhat lower price. He tells us, "that they used formerly to send annually from Spain to Bruges more than 40,000 sacks, but that in this year the Spaniards, having made more cloth at home, had sent only 25,000 sacks, at 25 crowns each." The crown being 4*s.* and the shilling 1*s.* 0 $\frac{1}{4}$ d. of our money, this would be 10*l.* 1*s.* 1*d.* the sack of 364 pounds. The depreciation seems in truth to have arisen from a diminished demand for this wool in the Netherlands. The wools imported into the Netherlands from Spain were the lower or coarser kinds.

The superfine wools of Spain seem to have been first introduced among the Italian states. Thus Damianus a Goes in 1541, after having specified the 40,000 sacks to Bruges, as before-mentioned, adds, "and also to Italy, and other cities of the Netherlands, are annually sent about 20,000 sacks, of which those used in Italy, being of the choicest wool, are sold at from forty to fifty gold ducats each."

From this account, we have a fair opportunity of drawing two important inferences: the first is, that the Spanish wool which went to the Netherlands was, as we have before observed, of the coarsest kind, being of only half the price of that which was exported to Italy; secondly, we can compare the value of the latter with that of our English wool, the best of which, according to the act of parliament in 1534, already quoted, did not in England exceed 5*s.* the stone of 14 pounds, of 6*l.* 10*s.* the sack of 364 pounds. The shilling, however, being then equal to 1*s.* 4 $\frac{1}{2}$ d. of our coin, increases the price of the sack 8*l.* 18*s.* 9*d.*; to which add custom and subsidy, 3*l.* 13*s.* 4*d.* or 5*l.* 0*s.* 10*d.*, and the result will be 13*l.* 19*s.* 7*d.* The additional charges of freight and merchant's profit would scarcely bring the whole amount to 16*l.* 16*s.* On the other hand, according to the testimony of Damianus a Goes, the Spanish sack of 181 $\frac{1}{2}$ pounds was in 1541 worth 14*l.* 6*s.* 5 $\frac{1}{2}$ d., and the sack of 364 pounds 28*l.* 14*s.* 6*d.* of our present money. If the author speaks only of the value of this wool in Spain itself, then a farther addition must be made of freight, merchant's profit, and probable duty to the crown. On the whole, this calculation is sufficient to shew in the strongest light the superior price of superfine Spanish wool, to that of the very best at that time produced in Britain.

Next in order of time to the Italians, the manufacture of superfine wool seems to have been adopted by the French, who, according to Guicciardini, in 1560 sent by land to Antwerp some very fine cloths of Paris and Rouen, which were highly prized.

It is probable, however, that these cloths were made only of mixed wool.

A strong confirmation of the early use of the best Spanish wool, unmixed with coarser by the Italian states, is furnished by Richelieu's Political Testament, printed in 1635, in which, speaking of the fine woollen manufactures of France, the author says, "the Turks prefer the draps de sceau de Rouen to all others, next to those of Venice, which are made of Spanish wool."

And the author of "England's Safety in Trade's Increase," written in 1641, tells us, that "the greatest part of their (the Venetians) wools from Spain, and the rest from Constantinople, is commonly brought in English shipping."

In 1646, Nicholas Cadeau and other Frenchmen had letters patent for twenty years, for making at Sedan black and coloured cloths, like those of Holland, of the finest Spanish wool.

The inhabitants of the north of Europe, as before-mentioned, were not at first able to manufacture fine Spanish wool, without the assistance of that which was longer and coarser. But what in the beginning was a matter of necessity, became afterwards an object of choice; and the more skilful clothiers, whether in Holland or elsewhere, either carding the finer and dearer Spanish with the coarser and cheaper English, or forming a warp of the latter, which they covered with a woof of the former, contrived to make a cheap and serviceable cloth, which pleased the eye equally well with the more costly fabrics of entire Spanish wool. This though generally concealed with great care at the time, yet is afterwards candidly acknowledged by writers actually engaged in the commerce of wool, and sufficiently refutes the prejudices which had here prevailed from the middle of the 16th to the middle of the 17th century. Hence it appears that our wool, when placed in connection with Spanish, was chiefly valuable from being well calculated not to improve but to adulterate it.

A treaty between France and Spain in 1659, enabled the former freely to obtain the wool of the latter, and thus to gain great advantage over us in the Levant trade. From the proximity of France to the woollen manufactures in the north of Spain, it might have been expected that the French would have earlier engaged in this manufacture; but owing to their frequent northern wars, and their attention being directed to the manufacture of silk, the French do not appear to have commenced the fabrication of woollens for exportation extensively before the 16th century. About this time, France made great progress in her manufactures of wool, and in securing the export trade, particularly that to Tartary, for which she was better situated than Holland or England.

The nature of her trade to warm climates directed her attention to the fabrication of finer and lighter cloths, than those made by her northern neighbours; in consequence of which she preserved the greater part of the Turkey trade to the period of the French revolution, and in general fine French cloths had attained a celebrity for their superiority, both in texture and dye, over those of any other country in Europe. The native breeds of sheep in France were greatly improved by intermixture with sheep imported from Spain. With these advantages, France might have nearly secured a monopoly of the finer branches of the woollen manufacture, had not the absurd policy of her rulers, in the revocation of the edict of Nantz, driven the manufacturing Protestants to other countries, where they contributed, by their exertion, their skill, connections, and capital, to form establishments which rivalled those of the country from which they were expelled.

Notwithstanding this, as France supplied the greater part of her own population of twenty millions with cloth, besides her foreign exports, we conceive that the woollens manufactured in that country, before the late revolution, equalled in quantity the cloth made in England at the time, and greatly exceeded it in value. Under the emperor Napoleon, the best Merino stocks were imported in multitudes from Spain, which have spread over the country, and are equal to supply extensively her manufactures of woollens, when they shall be again fully established. Considerable quantities of fine wool have been imported from France into England since the peace of 1815.

WOOLLEN MANUFACTURE.

The confusion attendant on a great revolution, continued for twenty years, gave so severe a blow to the manufacturing establishments of France, that a considerable time must elapse before they are completely established. Prior to this revolution, the superfine cloths of France were superior to those of England, in texture, colours, and softness. In the finer articles of worsted goods, and in the mixed worsted goods made partly with long combing-wool, and partly with silk or goat's-wool from the Levant, they surpassed the manufactures of this country; but the manufacturers of the commoner kinds of worsted goods, as tammies and shalloons, could not rival us in foreign markets for want of a proper supply of wool suited to the purpose. The following were the principal seats of the superfine and fine woollen manufactures in France, arranged according to the different qualities of the goods made at each, beginning with the finest:

1. The manufactures of Gobelins.
2. Of Sedan.
3. Of Abbeville.
4. Of Louviers.
5. Of Elbœuf.
6. Of Rouen and Darnetal.

Besides several detached manufacturing establishments of superfine cloth in Languedoc, Champagne, and other parts of France.

At the Gobelins, superfine cloths of the very first quality were manufactured; but the manufactures there were confined solely to the broadest white cloth intended to be dyed scarlet or purple, and the brightest colours from cochineal.

Sedan followed next to Gobelins for the beauty of its superfine cloths, where they were also made of various breadths and colours.

Abbeville may be placed next after Sedan: some have even supposed that it equalled Sedan in the fineness of its cloths; but this arose from the cloths of the latter place being of various sorts: the lower kinds were certainly inferior to those of Abbeville; but the quality of the greater part of the cloths of Sedan were of a better kind than the average quality of the cloths of Abbeville. In the manufactures of Sedan, each manufacturer confined himself to a particular kind of cloth, for which he became distinguished, some being celebrated for fine, and others for superfine cloths exclusively; whereas in Abbeville, Louviers, and the other districts enumerated, there were manufacturers who made various sorts, and the proportion of the fine to the superfine was greater than at Sedan.

Elbœuf was one of the most ancient seats of the woollen manufacture in France, but the quality of the cloths made there had greatly degenerated from the years 1760 to 1770; but afterwards the manufacturers returned to the former quality of their cloths, which were partly made of the fine wools from Bessy, and partly from fine Spanish wool, or from a mixture of Spanish with the best wools of Berry.

Rouen and Darnetal may be placed in the sixth class of manufacturing districts of fine cloth, in which the finest wools of France were principally used, mixed with those of Spain.

The establishments for the manufacture of common cloth and coarse woollens were much more widely spread over France. The goods appear to have been principally consumed in that country to supply the demand of a population of twenty millions, and the numerous military establishments, besides what might be sent to the French colonies.

As the French never exported any considerable quantity of common or coarse woollen cloths, the manufactures of these articles never equalled in extent those of England. The circumstance of the coarse cloth manufacture being so widely spread over the country, tended also to prevent that degree of rivalry which promotes the spirit of improvement where manufactures are more concentrated; add to this, the French had not that abundant supply of the coarser clothing-wools which could enable them to rival us in the export of heavy woollen goods.

The worsted manufactures of France, including ferges and those goods made with a warp of worsted, were principally carried on in four of the provinces of France, but more extensively in Picardy than elsewhere. The long combing-wools which supplied this manufacture, were partly the produce of France, and partly imported from Holland, England, Flanders, and Germany. M. Rolland, in the French Encyclopædia, describing the French manufactures in the year 1783, soon after the American war, says, that during that war the English administration tacitly encouraged the exportation of wool to promote the interests of agriculture. He describes the French combing-wool as being coarser and more harsh than the wool of Holland, as wasting much more in the manufacture, and making goods of a very inferior quality. The combing-wools of England, though generally less found and fine, and of a less pure white, than those of Holland, were particularly well suited to some parts of the worsted manufacture.

The combing-wools from Germany were coarse and harsh, and only used in default of other supplies. Very fine worsted yarn was also obtained from Saxony and the environs of Gottingen; but this yarn was tender, and required to be mixed with worsted yarn from English or Dutch wool. The yarn of Turcoign was supposed to be Dutch, but was principally from Flanders and Artois. The goat's-wool came from the Levant, by way of Marseilles, in bales of from 200 to 300 lbs. It sold from four livres to twelve livres *per* French pound; and the price of that most generally used was about 4 livres 10 sous *per* pound. The silks used in silk camelots, &c. were obtained from Paris and Lyons.

The following table gives the quantity and value of wool yarns and worsted pieces in Picardy; but he supposes the quantity to be under the real amount, the manufacturers concealing the extent of their trade to avoid arbitrary taxation.

Wool consumed in the Worsted Manufactures of Picardy.

	fous.	livres.
French wool	3200000 at 22	3520000
Dutch ditto	180000 at 40	360000
English ditto	200000 at 32	320000
German ditto	100000 at 22	110000
	3680000	4310000

Yarn imported.

	liv. s.	
Yarn of Turcoign	60000 at 8 10	510000
German yarn	100000 at 7 0	700000

4 M 2 Brought

WOOLLEN MANUFACTURE.

Brought forward	7430000
Combing and spinning 3680000 lbs. of wool	4310000
Winding, warping, and weaving	4770000
Dyeing of yarn and pieces	1900000
Profit of the wool-dealers, manufacturers	1300000
<hr/>	
Total value of 150000 pieces coming from the manufacturer	18000000
Value of dyeing-wares	5000000
To which carriage and profit of the merchant and draper	2000000
<hr/>	
Total value of worsted goods in Picardy	20500000

One million and fifty thousand pounds weight of wool were also consumed in hosiery in the same province, of which the greatest part was native; and the remainder about two hundred and fifty thousand pounds weight from Holland. The number of working manufacturers in Picardy is thus stated:

50000 men who gain 140 livres <i>per annum</i>	7000000
50000 women	3500000
150000 children	6000000

The greater part of the manufacturers resided in the country, and were employed part of the time in agriculture; this was also the case with the manufacturers in the towns, so that not more than eight months in the year were devoted to manufactures. This change of employment, so conducive to the health and comfort of the labouring classes, may be regarded as presenting the happiest form under which manufactures can be carried on. This was also in a considerable degree the situation of the woollen and worsted manufacturers in Yorkshire, before the late introduction of machinery had driven the population into large factories; a change which may be regarded as one of the greatest evils that ever afflicted civilized society, tending directly to degrade and enfeeble the human race, and to render man a wretched machine, a prisoner from the cradle to the workhouse or the grave, devoid of moral feeling and physical energy.

What was the extent of the worsted manufacture in the other provinces of France where it was carried on, we have no correct means of ascertaining. In the middle of the last century, the export of cloths and worsted goods from Languedoc alone amounted annually to about 60,000 pieces, sent to the Levant and to Barbary. At that time also, Spain, and all the countries bordering the Mediterranean, received worsted goods from France. In the variety of worsted articles, in the ingenuity of the patterns, and the superiority of the workmanship, as well as of the dyes, France may be regarded as having surpassed any other nation in Europe, prior to the year 1780, or about the close of the American revolution. Since that period, the manufactures of England have astonishingly increased, and have obtained a decided preference in foreign markets.

The woollen manufactures of Saxony and Germany have been long established; the fugitives from the edict of Nantz contributed much to improve and extend them. During the late war, all the manufactures in Germany and every part of the European continent suffered greatly, but are at present rapidly reviving, and will abridge the amount of our exports in Europe.

In Russia, Sweden, and Denmark, the woollen manufacture, as a distinct occupation, is comparatively new; yet it has existed long enough to produce great alteration

in their flocks. And as this change was attempted in a more enlightened period, and conducted by scientific men, the best means were adapted to promote the improvement, and new breeds of sheep have been introduced into both countries. The same remark applies to Saxony and other circles of the German states, and even Hungarian flocks are not without evident indication of a change for the better.

Of the worsted manufacture as distinct from the woollen, we have little information respecting its origin. It comprises all those goods made of combed wool in distinction from carded wool. We are unacquainted with the period when the wool-comb was invented, or when worsted goods were first manufactured. It is probable, that worsted goods were originally woven in the East, and that the knowledge of them was brought into Europe either by the Armenian merchants, or those who returned from the extravagant expeditions which were undertaken for the recovery of the Holy Land from the dominion of the infidels. The garments which are now worn by the Turks, some of which seem to have been produced by means of the comb, the incidental mention of that instrument in an account which we have of Angora, and the demand for worsted goods through the Levant, confirm the conjecture, and lead us to suppose, that there exist very considerable manufactures of this kind in the Turkish empire, although we know little more of its domestic and rural condition, than can be obtained from the most vague accounts and uncertain deductions. After the art of spinning worsted yarn was known in the west of Europe, the looms of the Netherlands became active in converting it into those peculiar kinds of goods to which it was adapted, and it seems as though the distinction between these and woollen articles was not generally noticed until some years afterwards. It might have been expected from the nature of the article, that the manufacture of worsted goods should in many southern countries have preceded that of cloth. Long-stapled wool suited to the comb seems more spontaneously the produce of uncultivated sheep, than short wool, which is to be manufactured by carding, and its mode of manufacture more nearly resembles that of flax; hence it is not improbable, that worsted goods were made in Egypt and the East before the manufacture of woollen cloth. This is, however, uncertain.

In the manufacture of long wool, the fibres are arranged parallel to each other, like those of flax; but before they are spun, they require to be laid even by some kind of instrument, which shall separate the fibres, that they may draw out easily in spinning. A comb of a very simple construction, with a few wires for the teeth, was probably first made use of. It was afterwards found, that the application of heat to the comb contributed more effectually to the regular arrangement of the fibres; and thus the invention of the common wool-comb arose, but at what period is unknown. Vulgar tradition ascribes the invention to bishop Blaize, who first used it in Alderney; but there does not appear any authority in support of this opinion. The bishop lived in Armenia, and was raised to the episcopal dignity about the time of Dioclesian, and suffered martyrdom under that tyrant. Before he was beheaded, he was tortured with iron combs, with which his flesh was torn; and hence when an instrument of that kind was brought into common use, the workmen chose him for their patron saint. The traditions of the origin and progress of the worsted manufacture are thus extremely imperfect; we shall have occasion to speak of its introduction and progress in this country in the following section.

WOOLLEN MANUFACTURE.

Rise and Progress of the Woollen Manufactures in England.

—The Romans, as we have stated on the authority of Camden, had a cloth manufacture at Winchester. The first account of any distinct body of manufacturers afterwards occurs in the reign of Henry I., but either the people of this country were wholly clothed in skins or leather in the intervening space, or, what is more probable, coarse cloths were manufactured in a rude manner in most of the towns and villages in England. A great part, however, of the dress of the labouring classes in the country was made of leather, particularly the breeches and waistcoats, even till the present reign. George Fox, the founder of the Quakers, in the reign of Charles I., travelled on his missions through the country, buttoned up in a leathern doublet, or waistcoat with sleeves, which supplied the place of a coat. This was not, as his adversaries afterwards affirmed, from any superstitious prejudice respecting that costume; it was the common dress of the labouring mechanics at that time, to which class he belonged.

The first account of any foreign weavers settled in England is recorded by William of Malmesbury and Giraldus Cambrensis, who relate that a number of Flemings were driven out of their own country, by an extraordinary encroachment of the sea in the time of William the Conqueror. They were well received, and first placed in the neighbourhood of Carlisle, and on the northern frontier; but not agreeing with the inhabitants, they were transplanted by Henry I. into Pembroke-shire. They are said to have been skilful in the woollen manufacture, and are supposed to have first introduced it into England as a separate trade. Cloth-weavers are mentioned in the exchequer accounts as existing in various parts of England in the reign of Henry I., particularly at London and Oxford. The weavers of Lincoln and Huntingdon are represented as paying fines for their guild in the 5th of Stephen; and in the reign of Henry II. (1189), there were weavers in Oxford, York, Nottingham, Huntingdon, Lincoln, and Winchester, who all paid fines to the king for the privilege of carrying on their trade. (*Chronicon Pretiosum*, p. 64.) There were also cloth dealers in various parts of Yorkshire, Norwich, Huntingdon, Gloucester, Northampton, Nottingham, and Newcastle-upon-Tyne; also several towns in Lincolnshire, and at St. Alban's, Baldock, Berkhamstead, and Chesterfield, who paid fines to the king that they might freely buy and sell dyed cloths. These are supposed to have been cloths imported from the Flemings. The red, scarlet, and green cloths, enumerated among the articles in the wardrobe of Henry II., were most probably foreign, as the English had attained little skill at that time in the art of dyeing. Madox's History of the Exchequer.

In the 31st of Henry II. the weavers of London received a confirmation of their guild, with all the privileges they enjoyed in the reign of Henry I.; and in the patent he directed, that if any weaver mixed Spanish wool with English in making cloth, the chief magistrate should seize and burn it. (*Stowe's Survey of London*.) This absurd edict was issued under the pretext of the inferiority of the Spanish wool, but was doubtless intended to encourage the growth of English wool, an article from which our kings derived a considerable revenue. The circumstance rather proves the superior excellence of Spanish wool at that time, and the jealousy which its importation had excited among the English wool-growers.

In the reign of Henry III. an act was passed limiting the breadth of broad-cloths, ruffs, &c. to two yards within the lists. In the year 1284, foreign merchants were first permitted to rent houses in London, and buy and sell their

own commodities, without any interruption from the citizens. Previous to this date they hired lodgings, and their landlords were the brokers, who sold all their goods, and received a commission upon them. It was soon after pretended that the foreign merchants used false weights, and a clamour being raised against them, twenty of them were arrested and sent to the Tower. Amidst the numerous absurd restrictions to which commerce and manufactures were subjected, we need not be surprised at the little progress which they made.

The materials which history affords respecting the woollen manufacture before the reign of Edward III. are but scanty; it appears that the office of aulnager, or cloth inspector, was very ancient. In the reign of Edward I. we are informed by Madox, that Peroult le Tayleur, who held the office of aulnager of cloth in the several fairs of the realm, having forfeited it, the king, by writ of privy seal, commanded the treasurer to let Pieres de Edmonton have it, if he were fit for it, and a writ was made out accordingly, and he took the oaths of that office before the treasurer and barons. The facts above-stated prove the existence of the cloth manufacture in England before the time of Edward III., who is generally supposed to have first introduced the art into the kingdom. There is no doubt, that a new impulse was given to it during this reign by the liberal protection granted to foreign manufactures here: in all probability, they first introduced the manufacture of stuffs from combed wool or worsteds; an art requiring more skill, and more complicated processes, than are employed in the making of cloth.

In the year 1331, John Kemp, a master manufacturer from Flanders, received a protection to establish himself here with a number of dyers and fullers to carry on his trade, and in the following year several manufacturers came over from Brabant and Zealand. It is said, that the king's marriage with the daughter of the earl of Hainault enabled him to fend over emissaries without suspicion, to invite the manufacturers to this kingdom. These manufacturers were distributed over the country, at the following places:—The manufacturers of fustians (woollens) were established at Norwich, of baize at Sudbury in Suffolk, of sayes and ferges at Colchester in Essex, of broad-cloths in Kent, of kerseys in Devonshire, of cloth in Worcestershire and Gloucestershire, of Welsh friezes in Wales, of cloth at Kendal in Westmoreland, of coarse cloths, afterwards called Halifax cloths, in Yorkshire, of cloth in Hampshire, Berkshire, and Suffex, and of ferges at Taunton in Devonshire. (*Rymer's Fœdera*, vol. i. p. 195.) Fresh supplies of foreigners contributed to advance the woollen trade of these districts.

Kendal, in Westmoreland, claims the honour of first receiving John Kemp, where his descendants still remain, and the woollen trade is at present carried on. In the following reign, we find the manufacturers of Kendal petitioning to be relieved from the regulations imposed on broad-cloths. Kendal green is mentioned by Shakspeare as an article of dress in the time of Henry IV., and there is reason to believe, that in the reign of Elizabeth, the woollen manufactures of that town were as extensive as at present.

In the year 1336, two woollen manufacturers from Brabant settled at York, under the king's protection: they are styled in the letters of protection, "Willielmus de Brabant & Hanckcinus de Brabant, Textores." These persons probably laid the foundation of the woollen and worsted manufactures, which have since so extensively flourished in the western part of that county. It is not very improbable, that the manufacturer Hancks, called Hanckcinus,

gave

WOOLLEN MANUFACTURE.

gave the name to the skein of worsted, which is to this day called a hank.

The references which we have soon afterwards to the woollen manufacture, as existing in the districts before-named, tend to confirm the belief, that the distribution of the foreign manufacturers we have given is correct. About this time, we learn that Thomas Blanket, and other inhabitants of Bristol, set up looms in their own houses, but were so harassed by the impositions of the mayor and bailiffs of the place, that they were obliged to obtain letters from the king to permit the free use of their trade, without impediment, calumny, or exaction. The letter to the mayor and bailiffs accuses them in the following terms: "vos diversas pecunie summas ab eisdem Thomas et aliis exigitis et ea occasione multipliciter inquietatis et gravatis, ut asserunt." Dr. Parry has conjectured, that blanket, which at first meant a coarse white undressed cloth, derived its name from the same Thomas Blanket of Bristol. The encouragement given to the woollen manufacturers during this reign, and the consequent consumption of wool at home, diminished the export of it so much, that a duty was laid on cloth exported to supply the place. Blackwell-hall was appointed by the mayor and common council of London for the market, where cloth manufacturers might send their goods for sale, in the year 1357.

In the course of the reign we find several other acts relating to the measurement and fulling of cloth, and the fees to be paid to the aulnager.

In order to form a more distinct idea of the relative value of wool, cloth, and other articles, after and before the reign, it may be proper to refer to the state of the silver coinage.

at which it continued to the present reign.

The following account of the exports and imports in the 28th of Edward III., said to be found in a record of the exchequer, was published by Edward Misseldon, merchant, in the year 1623.

<i>Exports.</i>	£	s.	d.
Thirty-one thousand six hundred and fifty-one sacks and a half of wool, at six pounds value each sack, amount to	189,909	0	0
Three thousand thirty-six hundred and sixty-five felts at 40s. value, each hundred at six score, amount to	6,073	1	8
Whereof the custom amounts to	81,624	1	1
Fourteen last, seventeen dicker, and five hides of leather, after six pounds value the last, amount to	89	5	0
Whereof the custom amounts to	6	17	6
Carried forward	277,702	5	3

	£	s.	d.
Brought forward	277,702	5	3
Four thousand seven hundred and seventy-four cloths and a half, after 40s. value the cloth, is	9,549	0	0
Eight thousand and sixty-one pieces and a half of worsted, after 16s. 8d. value the piece, is	6,717	18	4
Whereof the custom amounts to	215	13	7
Summary of the out-carried commodities in value and custom	294,184	17	2

Imports.

One thousand eight hundred and thirty-two cloths, after six pounds value the cloth	10,922	0	0
Whereof the custom amounts to	91	12	0
Three hundred and ninety-seven quintals and three quarters of wax, after the value of 40s. the hundred or quintal	795	10	0
Whereof the custom is	19	17	0
One thousand eight hundred and twenty-nine tons and a half of wine, after 40s. per ton	3,659	0	0
Whereof the custom is	182	0	0
Linen cloth, mercury, and grocery-wares, and all other manner of merchandize	23,014	16	0
Whereof the custom is	285	18	3
Summary of the in-brought commodities, in value and custom, is	38,970	13	3
Summary of the impulfage of the out-carried above the in-brought commodities, amounteth to	255,214	3	11

Admitting the correctness of this statement, which we have no reason to doubt, we must observe, that the cloth imported was of a higher value *per* yard than the cloth exported. Hence it may be inferred, that for several years after the arrival of the Flemish weavers, we were partly dependent on foreigners for our fine cloths; the coarser kinds then, as at the present day, forming the larger quantity of our exports. It is obvious also, that worsted goods had become an article of manufacture, nearly equal in importance with the woollen; and hence it is not improbable, that the greater part of the Flemish manufacturers were makers of stuffs and worsted goods, which was probably an entirely new trade in England.

The statutes in the following reigns, relating to the woollen manufacture, prove the narrow and selfish policy by which the manufacturers were influenced: these statutes refer either to restrictions which they wanted to impose, in order to confine the trade to themselves, or are made to prevent them from fraudulently packing or weaving their goods. In consequence of these fraudulent practices, the 13th statute of Richard II. makes the following regulations, which are curious, as marking the spirit of the manufacturers, and also as proving the early establishment of the woollen trade in the western counties, where it now flourishes. It runs thus: "Forasmuch as divers plain cloths, wrought in the counties of Somerset, Dorset, Bristol, and Gloucester, be tacked and folded together for sale; of which cloths a greater part be broken, bruised, and not agreeing in the colour, neither according to the breadth, nor in no manner to the part of the same cloths shewed outwards, but falsely wrought with divers wools, to the great loss and damage

WOOLLEN MANUFACTURE.

damage of the people, inasmuch that the merchants that buy the same, and carry them out of the realm to sell to strangers, be many times in danger to be slain, and sometimes imprisoned and put to fine and ransom. Therefore it is ordained, that no plain cloth tacked and folded shall be set to sale within the same counties." The same act permits certain cloths of coarse wool to be made of the breadth of three quarters, and appoints one weight and measure through the kingdom, except in the county of Lancaster. Another statute, in the same reign, allows every person to make cloth of what length and breadth he will, provided the aulnage and other duties are paid, and it be measured and sealed by the king's aulnager, and contain no deceit. The kinds of worsted goods which might or might not be exported, were also specified in this statute. During this reign it appears, notwithstanding the increase of our trade, that we annually exported about one hundred and thirty thousand packs of wool, paying a duty of one hundred and sixty thousand pounds.

In the 4th of Henry IV. the cloths made in London and the suburbs were ordered to have a seal of lead attached, and in a subsequent statute no cloths were to be folded before the aulnager had set his seal to them. In the following reign, the narrow cloths, called the dozens of Devonshire and Cornwall, are ordered to pay cocket customs, after the rate of broad-cloths.

In the reign of Henry VI. the exportation of woollen yarn is prohibited, and this prohibition seems to have been in full force when wool was allowed to be freely exported. The only reason assigned for this is, that the yarn paid no duty. During this reign two cloth-searchers were appointed for every hundred throughout the realm, who were to inspect and seal all cloth, taking one penny for each. This proves that the manufacture of woollens had spread over a great part of the kingdom. It is probable that this inspection extended to all cloths made in private families, which were sent to the fulling-mills.

The worsted trade was also increasing rapidly at this time: four wardens of worsted-weavers were appointed for the city of Norwich and two for the county of Norfolk, who were to make due search of worsteds, and of what length and breadth they were made. In the same reign it was ordained, that "if our woollens were not received in Brabant, Holland, and Zealand, then the merchandize growing or wrought within the dominions of the duke of Burgoine shall be prohibited in England, under pain of forfeiture." Hence we learn, that we very soon began to supply these same countries with woollens and worsteds, from which we had received workmen a century before.

In the third year of Edward IV. the woollen trade had increased so much, that the importation of woollen cloth, caps, &c. was prohibited. Woollen caps or bonnets were then universally worn; they were either knitted or made of cloth, and a large quantity of wool must have been consumed in their fabrication. About the year 1482, hats made from felts were introduced; but the manufacturers of caps, called the cappers, continued a powerful body a century afterwards. In the same reign, the wardens of worsteds at Norwich were doubled, or increased to eight.

The manufacture of fine broad-cloth must have been considerably improved about this time; for in the fourth of Henry VII. it was thought prudent to fix a maximum on the price of fine cloth, by which every retailer of cloth who should sell a yard of the finest scarlet grained cloth above sixteen shillings, or a yard of any other coloured cloth above eleven shillings, was to forfeit forty shillings *per* yard for the same.

In the year 1493, in consequence of a quarrel between Henry VII. and the archduke Philip, all intercourse between the English and Flemish ceased, and the mart for English goods was transferred from Antwerp to Calais. This interruption to the regular course of trade was severely felt by the woollen manufacturers. Lord Bacon, mentioning the renewal of the trade with Flanders, which took place again in 1496, says, "By this time the interruption of trade between the English and Flemish began to pinch the merchants of both nations very sore. The king, who loved wealth, though very sensible of this, kept his dignity so far as first to be fought unto. Wherein the merchant adventurers likewise did hold out bravely; taking off the commodities of the kingdom, though they lay dead upon their hands for want of vent." The merchant adventurers he describes as "being a strong company, and underfet with rich men." It is not, however, very probable, that this company would continue to purchase goods without a prospect of gain. These merchant adventurers were divided into two bodies; those of London, which were the most powerful; and the merchant adventurers of England, who paid a fine to the former on all goods sold at the foreign marts.

In the reign of Henry VIII. the woollen trade, and particularly all kinds of worsted manufactures, appear to have been in a very flourishing state, though trade suffered several severe checks from the wars in which we were engaged. In the year 1527, Henry having entered into a league with France against the emperor Charles V., all trade with Spain and the Low Countries ceased. The goods sent to Blackwell-hall found no purchasers, the merchants having their warehouses filled with cloths; the poor manufacturers being thus deprived of employment, an insurrection took place in the county of Suffolk, where four thousand of them assembled, but were appeased by the duke of Norfolk. The merchants were summoned to appear before cardinal Wolsey, who in the name of the king reprimanded them in an angry tone for not purchasing the goods brought to market, and threatened them that his majesty would open a new mart at Whitehall, and buy of the clothiers to sell again to foreign merchants; to which menace one of them pertinently replied, "My lord, the king may buy them as well at Blackwell-hall, if it pleases him, and the strangers will gladder receive them there than at Westminster."—"You shall not order that matter," said the cardinal; "and I shall send into London to know what cloths you have on your hands, and by that done, the king and his council shall appoint who shall buy the cloths, I warrant you." With this answer the Londoners departed. Grafton's Chronicle, vol. ii. p. 1167-8.

The interference of the cardinal raised the spirits of the manufacturers for a time, but originating in ignorance of the nature of trade, it could only have a temporary effect, and goods fell again till a truce between England and Flanders was made for the benefit of trade. This fact shews the dependance of England, even at that time, on the export of manufactured woollens. In this reign we find Lancashire and Cheshire first named as seats of the manufacture of coarse woollens; they are mentioned, together with Cornwall and Wales, as districts where friezes were made. It appears from various references, that Norfolk and Suffolk were then flourishing seats of the worsted manufacture, and of all goods made with a worsted warp. Wardens were allowed to the towns of Yarmouth and Lynn, but with a selfish restriction, that the pieces were to be dyed, spun, or callendered in the city of Norwich. In the last year of this reign, an act was passed to prevent any persons

persons besides woollen manufacturers, who bought wool for their own use, and merchants of the staple, who bought for exportation, to purchase wool with the intent to sell again. This act extended to twenty-eight counties, and secured a monopoly of the wool to the merchants of the staple, and to the rich clothiers. In the first year of the following reign, Edward VI., it was repealed, so far as to allow every person dwelling in Norwich and Norfolk, to buy wool the growth of that county, by themselves or agents, and retail it out in open market. The reason assigned is this: That almost the whole number of poor inhabitants of the county of Norfolk and city of Norwich had been used to get their living by spinning of Norfolk wool, which they used to purchase by eight pennyworth or twelve pennyworth at a time, selling the same again in yarn; and because the grower chose not to parcel it in such small quantities, therefore for the benefit of the poor, the wool of Norfolk was allowed to be purchased by wool-dealers. By this act, the 33d of Henry VIII., for prohibiting the exportation of yarn is made perpetual. The manufacture of woollens in the counties adjoining London appear to have been extensive, particularly in the county of Berkshire; for in the beginning of the reign of Henry VIII., John Winchcombe, of that county, commonly called Jack of Newbury, was celebrated as the greatest clothier in England. He kept one hundred looms in his own house, and in the expedition against the Scotch, he sent to Flodden-field one hundred men, fully equipped, at his own expence. Even so early as the 13th century, one Thomas Cole was distinguished by the name of the rich clothier of Reading, in Berkshire.

York, then the second city in the kingdom, and from its connection with the port of Hull well situated for the export trade, was probably an early seat of the woollen manufacture. We have already mentioned the settlement of two clothiers from Brabant in the time of Edward III. We do not learn precisely in our early historians, when the manufactures emanated from that city into the western parts of the county; but from an act in the 34th of Henry VIII. we are informed, that the chief manufacture of that city was the making of coverlets; the act recites, "that the poor of that city were daily employed in spinning, carding, dyeing, weaving, &c. for the making of coverlets, and that the same have not been made elsewhere in the said county till of late; that this manufacture had spread itself into other parts of the county, and was thereby debased and discredited, and therefore it is enacted, that none shall make coverlets in Yorkshire but the people of York." Thus we see, under the flimsy pretext of public benefit, the manufacturers were willing to disguise that selfish spirit of monopoly, which disgraces almost every page of our commercial history. The municipal regulations of the city of York, which were, and still continue to be, hostile to a free trade, probably obliged many manufacturers, who were not sharers in the monopolies of the guild, to establish themselves in the western villages of the county, where provisions were cheaper, and where they could carry on their trade without restriction. In the reign of Philip and Mary, soon after this period, we have the following interesting account of Halifax, in consequence of an act passed in the 37th of Henry VIII. to prevent any other persons than merchants of the staple and woollen manufacturers from buying wool in the county of Kent and twenty-seven shires. The poorer manufacturers, who were unable to lay in their stock of wool at one time, being hereby deprived of their trade, made application for redress, which was granted. The act recites as follows: "Whereas the town of Halifax being

planted in the great waste and moors, where the fertility of the ground is not apt to bring forth any corn nor good grafs, but in rare places, and by exceeding and great industry of the inhabitants; and the same inhabitants altogether do live by cloth-making, and the greater part of them neither getteth corn, nor is able to keep a horse to carry wools, nor yet to buy much wool at once, but hath ever used to repair to the town of Halifax, and there to buy some two or three stone, according to their ability, and to carry the same to their houses, three, four, or five miles off, upon their heads and backs, and so to make and convert the same either into yarn or cloth, and to sell the same, and so to buy more wool of the wool-driver; by means of which industry, the barren grounds in those parts be now much inhabited, and above five hundred households there newly increased within these forty years past, which now are like to be undone and driven to beggary by reason of the late statute (37th of Henry VIII.) that taketh away the wool-driver, so that they cannot now have their wool by such small portions as they were wont to have, and that also they are not able to keep any horses whereupon to ride or fetch their wools further from them in other places, unless some remedy may be provided. It was therefore enacted, that it should be lawful, to any person or persons inhabiting within the parish of Halifax, to buy any wool or wools at such time, as the clothiers may buy the same, otherwise than by engrossing and forestalling, so that the persons buying the same do carry the said wools to the town of Halifax, and there to sell the same to such poor folks of that and other parishes adjoining, as shall work the same in cloth of yarn, to their knowledge, and not to the rich and wealthy clothier, or any other to sell again. Offending against this act to forfeit double the value of the wool so sold."

From this we learn that many woollen manufacturers had been either driven from York at an early period, by the oppression of the municipal regulations, or had retired where provisions were cheaper, and where they had better streams for the erection of fulling-mills, and for other processes of the manufacture, such as dyeing and scouring.

The woollen manufactures also gradually retired from the vicinity of the metropolis, owing to the increased price of provisions and labour, and probably also to the difficulty of obtaining commodious streams for the scouring and fulling of cloth, when the country round London became more populous. In the latter part of the reign of Henry VIII. we are informed, that the king demised to William Webbe the subsidy and aulnage of all cloth made in the county of Monmouth, and in the twelve shires of Wales. A former act of this reign, speaking of the manufacturers of North Wales says, they had been used to sell their cloths so craftly and hard rolled together, that the buyer could not perceive the untrue making thereof. These acts prove the extension of the woollen manufactures westward.

In the same reign, an act mentions the woollen manufactures as being established in Worcestershire, but prohibits any one from making cloth in the county, except within the city of Worcester, and in the towns of Evesham, Droitwich, Kidderminster, and Bromsgrove; and forbids the owners of houses in those places from letting them at advanced prices to the cloth-manufacturers. The woollen manufacture has continued to the present day at the two last of these towns. In the reign of Edward VI. Coventry and Manchester are mentioned as manufacturing places. The manufacturers in the old established seats of the woollen trade appear to have been greatly alarmed at the extension of the cloth manufacture, and to have exerted all their influence to restrain it. Near the conclusion of the reign of Philip

Philip and Mary, an act in 53 sections was passed, relating to the making of woollen cloths. It enacts, that no person shall make woollen cloth but only in a market-town, where cloth hath commonly been used to be made for the space of ten years last past, or in a city, borough, or town corporate. From this restricting act, however, the following exceptions are made: to all persons who dwell in North Wales or South Wales, Cheshire, Lancashire, Westmoreland, Cumberland, Northumberland, the bishopric of Durham, Cornwall, Suffolk, Kent, the town of Godalmin in Surrey, or in Yorkshire, being not within twelve miles of the city of York, or any towns or villages near the river Stroud in Gloucestershire. This act, so absurd and oppressive, was obliged to be modified in the first year of the following reign, by an act entitled "An Act for the continuing and making of Woollen Cloths in divers Towns in the County of Essex." Bocking, Watherfold, Cockshill, and Dodham, are the towns specified.

In consequence of the increase of our manufactures, the export of wool had nearly ceased before the reign of Elizabeth; and a considerable advance appears to have taken place in the price of food, clothing, and rents. The export trade of England was carried on very extensively by three companies of merchants, the merchants of the Stillyard, who were foreigners, the merchants of the Staple, and the merchant adventurers, who were English. See **STILLYARD, STAPLE, and ADVENTURERS.**

The merchants of the Stillyard were of ancient standing, and were originally from the Hanse towns: they had great privileges granted them, and particularly they were allowed to export and import all wares and merchandize, on payment of the small duty of one and a quarter *per cent.* This gave them a decided advantage over the other companies; and it is alleged that they lent their name to cover the import and export of goods belonging to private merchants, and thereby evaded the regular duties on such goods. This company had engrossed a considerable part of the cloth trade. In the year 1551 they exported 44,000 cloths; soon after which this company was dissolved. The merchant adventurers succeeded to that branch of their trade: according to the account of John Wheeler, secretary to the company, there were annually shipped by them 50,000 white cloths, worth 600,000*l.*, and 40,000 cloths of all sorts, baizes and kerseys, worth 400,000*l.*, besides wool and woolfels. We are told by Camden, that, in his reign, the commerce between England and the Netherlands rose to above twelve millions yearly, and the woollen trade alone amounted to five millions. The Latin terms which Camden employs, *milliones aureorum*, leaves the amount intended uncertain: if we suppose it to be ducats, the quantity is much greater than England exported at that time; probably florins were intended, which makes the amount about 750,000*l.*

Besides the exports to Antwerp, English cloth was at this time sent to Amsterdamb, Hamburgh, Sweden, Russia, and other countries. The woollen trade of England had now advanced to a higher state of prosperity than at any former period; and from this time it appears to have declined until after the revolution of 1668. In this reign, the price of wool, which we believe to mean long or combing wool, had advanced from 13*s.* 4*d.* to 22*s.* *per* tod; and the shilling containing the same weight of silver as our late coinage, *viz.* 86 grains, the relative value of a tod of long wool was considerably more than it has ever been during the present reign.

The declension of our manufactures in the succeeding reigns of the Stuarts, as we have reason to believe, extended much more to woollen cloths than to worsted pieces. Long

wool, or combing-wool, was more the peculiar produce of England than clothing-wools. The latter were grown in abundance, and of a superior quality, in Spain, Portugal, and France; but the combing-wools of England, on account of the superior foundness of the staple or fibre, and the quantity supplied, gave a decided advantage to our manufacturers of stuffs or worsted pieces.

The persecution of the Protestants by the duke of Alva in the Netherlands drove multitudes of the manufacturers into England, where they were graciously received by Elizabeth, who gave them liberty to settle at Norwich, Colchester, Sandwich, Maidstone, and Southampton. These refugees contributed to extend our manufactures of worsted goods and light woollens, called bays and says; they also introduced the manufacture of linens and silks, and it is supposed that they first taught the art of weaving on the stocking-frame.

In the latter part of the reign of Elizabeth an act was passed to relieve the counties of Somerset, Gloucester, and Wiltshire, from those absurd and oppressive statutes which confined the making of cloth to corporate towns. This act, which gave to all persons residing in these counties the privileges of free trade, could not fail to extend and establish the woollen manufactures in these parts, and they have remained to the present time the principal seats of the superfine cloth trade, whilst many manufacturing corporate towns, which were then flourishing, have sunk to decay. Various acts, regulating the length, breadth, and tentering of woollen goods of different kinds, were also passed in this reign, referring to the counties of Oxfordshire, Devon, and the counties north of Trent, particularly Yorkshire and Lancashire. The importation of foreign wool-cards was also prohibited. The act recites, that many thousands of woollen card-makers and card-wire drawers, living in London, Bristol, Gloucester, Norwich, Coventry, and elsewhere, had heretofore subsisted themselves and families upon that business, which was now greatly impaired by the importation of wool-cards. No laws prohibiting the export of wool were thought necessary in this period of our history, and it continued to be exported during the whole of this reign, as appears by the account of the merchant adventurers, who exported it together with cloth; but though wool was freely exported, an act was passed to prevent the carrying of live sheep, lambs, or rams out of England; but the reasons for this act are not recited, though it states it was for divers good causes and considerations. The internal tranquillity that the country enjoyed during this long reign, the influx of foreign makers of new kinds of worsteds, and other articles not known before, the opening of a new trade to Turkey and the Barbary states, by treaty in the year 1579 and in 1585, all greatly contributed to the extension of the woollen trade and manufactures. There were indeed other circumstances which must have operated against our manufacturers in part of this reign. The interruption of commerce between England and the Netherlands in 1564, which lasted some time, the wars with Spain, the sacking of Antwerp, in which the English merchants suffered severely, gave a considerable check to the foreign trade; yet we have seen that the merchant adventurers alone exported woollens to the amount of one million sterling towards the latter end of this reign. The demand at home for woollens must also have greatly increased during the long period of domestic tranquillity which the nation at that time enjoyed, and particularly from the prevailing taste for costly dresses which has spread from the court through the country.

A great part of our woollen exports hitherto consisted of white undressed cloth; but in the following reign of James I. it was represented as bad policy to permit the exportation of cloth in this state, and thereby lose the profit on the

dyeing and finishing. A letter exists addressed to king James on this subject, ascribed to sir Walter Raleigh, but without sufficient evidence, as "the most ancient manuscripts of this letter in the libraries of the nobility ascribe it to John Keymer." (Oldy's Life of Sir W. Raleigh.) In this letter it is stated, "that there have been eighty thousand undressed and undyed cloths exported yearly, by which the kingdom has been deprived of four hundred thousand pounds for the last fifty-five years, which is nearly twenty millions that would have been gained by the labour of the workmen in that time, with the merchants' gains for bringing in dyeing-wares, and return of cloths dressed and dyed, with other benefits to the realm." The writer proceeds, in another part, to state, that there had also been exported in that time annually, of baizes and northern and Devonshire kerfies, in the white, fifty thousand cloths, counting three kerfies to a cloth, whereby had been lost about five millions to the nation in labour, profit, &c. The author informs us, that the baizes so exported were dressed and dyed at Amsterdam, and shipped to Spain, Portugal, and other kingdoms, under the name of Flemish baize, setting their own seal upon them; "so that we lose the very name of our home-bred commodities, and other countries get the reputation and profit thereof." The author concludes with asserting, that the nation loses a million a year by the export of white cloths, which might be dressed and dyed as well at home. This letter has been often quoted as containing unanswerable reasons for confining the whole process of the cloth manufacture to our own country; but, like other monopolists, the writer seems to forget that there are two parties in all mercantile transactions, and that manufactured goods must be sent in that state in which the purchaser is willing to receive them, unless it be proved that he cannot procure them elsewhere. Let us mark the result. Alderman Cockayne, and other London merchants, had sufficient influence with the government to obtain the prohibition of the export of white cloths, and to secure a patent for dressing and dyeing of cloths. In consequence of which, the Dutch and Germans immediately prohibited the importation of dyed cloths from England, which gave so great a check to our export trade, that in the year 1616, the whole amount of cloths exported of every kind amounted only to sixty thousand, so that the export trade in woollens had fallen to less than one-third of its former amount; and in the year 1622,

	l.	s.	d.
All our exports of every kind } amounted only to - }	2,320,436	12	10
Whilst our imports were -	2,619,315	0	0
Leaving a balance against us of	298,878	7	2

It being from experience proved, that the policy of dressing and dyeing all our goods at home had produced the greatest injury to the woollen trade, the restrictions were taken off, and the export for white cloth left free. In the former reign, cloths about four pounds value were, by statute, to be sent out dyed, by all persons except the company of merchant adventurers, who obtained a licence to export all sorts of white cloths; and though this was itself a monopoly, yet, as it gave foreigners an opportunity of receiving our finer cloths in the state which they most wanted, it was the means of increasing our trade: indeed it is said by Misselden, that "within a few years after granting this licence, the vent for cloth in foreign parts increased to twice as much as it had been during the strict observance of the statute." With this fact before their eyes, it is scarcely possible that our statesmen at that time could have proceeded to the pro-

hibition of white cloth exports, unless they had been (as was asserted) influenced by presents from alderman Cockayne and the rich merchants, who expected to receive the benefit arising from the prohibition, and the exclusive right of dyeing and dressing. The wool-growers equally felt the ill effects of this prohibition. Wool is said to have fallen from thirty-three shillings *per* tod to twenty shillings; if by this is meant the long combing-wools, the former price, considering the value of money at that time, is much higher than it has been in the last or the present century.

During the reigns of the Stuarts, the infamous policy they adopted struck not only at the liberty, but at the commercial prosperity of the country. Archbishop Laud, imbued with the malignant zeal of a bigot, commenced his attacks on the descendants of the French Protestants, established as manufacturers of woollens in Norfolk and Suffolk, from which counties his persecuting fury drove some thousand families. Many of them settled in New England; but others went into Holland, where they were encouraged by the Dutch, who allowed them an exemption from taxes and rents for seven years. In return for this, the states were amply repaid by the introduction of manufacturers, with which they were before unacquainted. In the year 1622, king James issued a proclamation to prohibit the exportation of wool, fuller's-earth, &c. In 1640 wool was again admitted to be exported on the payment of certain duties; and we are told, that in the same year sir John Brownlowe, of Belton in Lincolnshire, sold three years' wool at twenty-four shillings *per* tod to a baize-maker of Colchester. As it is reasonable to suppose that this was the long combing-wool of that county, it shews the high relative price of the article at that time. In 1647, owing to the high price of wool, its exportation was again prohibited.

During the civil wars, the manufactures and export trade of England declined, and the Dutch availed themselves of this to extend their own manufacture and export of woollens, particularly to Spain, from whence they brought fine Spanish wool. At this time it appears, that the woollen manufactures in Poland and Silesia were rapidly increasing; and the English government received information that two hundred and twenty thousand cloths were made there annually, besides considerable quantities made at Dantzic, and in the vicinity.

The duke of Brandenburg, it was also stated to our government, had ordered one hundred thousand ells of Silesia cloth at Königsberg for his troops, which had been heretofore supplied with English cloth. The estimation in which our cloth had been held is said to have been lost by negligence in the manufacture, particularly in the spinning and weaving. The Dutch and Poles had a little before this time received a great number of Protestant manufacturers, who fled from the persecution of the duke of Alva in Brabant and Flanders.

Here it may be proper to remark, that the English as a nation had little intercourse with other parts of the world, except through a few large trading companies: hence they were extremely ignorant respecting the state of foreign countries, and supposed that the cloth trade had been confined to their own country for three hundred years; and they considered the establishment of other manufacturers as a novelty and infringement of their just rights. With these views, it was proposed to obtain a complete monopoly of all the clothing-wool in Spain, in order to prevent the Dutch and other nations from rivalling our manufactures. This is the more extraordinary, as the English had not then learned, like the Dutch, to manufacture Spanish wool, without mixing it with that of their own country. It is needless to say, tha

WOOLLEN MANUFACTURE.

the negociation of fir William Godolphin for this selfish monopoly of wool was not successful. During the whole reign of Elizabeth, when our woollen manufactures were in the highest state of prosperity, wool and woofels were permitted to be exported. In the reign of James I. and Charles I., when the trade was declining, proclamations were issued to prevent the exportation of wool, and also that of fuller's-earth. During the commonwealth, an ordinance of parliament was issued to prohibit the exportation of wool and fuller's-earth, on pain of forfeiture of the wool, and a penalty of 3*s.* per pound on every pound of fuller's-earth. The first act of parliament which absolutely prohibited the exportation of wool by making it felony, and which could not be set aside by a royal licence, is the 12th of Charles II., which was passed soon after the Restoration.

The grounds of this measure are stated in the preamble of the act: "For the better preventing the losses and inconveniences which have happened by and through the secret and subtle exportation of wool out of the kingdom; and for the better setting to work the poor people and inhabitants of the kingdom, to the intent that the full and best use and benefit of the principal native commodities of the kingdom may redound to and be unto and amongst the subjects and inhabitants of the kingdom, and not unto any foreign states." Previous to this time, the proclamations and ordinances issued to prevent the exportation of wool, for the most part, signified nothing more than the imposition of a duty or a composition for exporting by licence from the government, what on other terms was forbidden, under penalties of confiscation, fine, or imprisonment. We have seen that, from the death of Elizabeth to the Revolution in 1688, the woollen trade was generally in a languishing state. In the year 1665, Thomas Telham of Warwickshire, with two thousand manufacturers, left the kingdom, and established themselves in the Palatinate, and commenced a woollen manufacture there, and were greatly encouraged by the elector. The establishment was soon afterwards joined by a number of manufacturers from Hertfordshire.

During the period from Elizabeth to the year 1668, the English appear to have made no improvement whatever in their modes of manufacture of woollen cloth, whilst the neighbouring nations had been making a gradual progression, both in the style of their manufacture, and the amount annually produced. It was especially in the manufacture of fine cloths that their superiority was manifest. The Dutch, in particular, were far more expert than the English in the dressing and dyeing of cloth. This will appear from the following remarkable fact stated by Coke, vol. ii. p. 169. In the year 1668, one Brewer, with about fifty Walloons, who wrought and dyed fine woollen cloths, came into England, and received the royal protection and encouragement. By him the English were first instructed how to manufacture cloth of the best Spanish wool, without any admixture with inferior wool; and also to manufacture and dye fine cloths cheaper by 40 per cent. than they had done before. Ten years before this time, it had been published and admitted in England, that "Spanish wool alone could not be wrought into cloth." It may seem truly extraordinary that the English, who had so long carried on the manufacture of woollen cloth, had not availed themselves of the revolution in Flanders, which drove away the best master manufacturers, to encourage their settlement in this country. M. Huet explains the fact in a way which is not very creditable to the liberality of the English manufacturers, or to the wisdom of our institutions. "It was owing to the municipal laws of England, and its usages towards strangers; who, besides being doubly rated at the custom-house, were excluded from all companies or fraternities of trade; and were

not allowed to carry on manufactures as masters or partners, unless such as the natives were unacquainted with; so that none of the Flemish master manufacturers of fine cloth went thither (to England), their's being a mystery not accounted new, though very much superior to the cloth working then known in England. It was only those who wrought in new kinds of worsteds, ferges, damasks, or stockings, who went thither. The same policy was also adopted by the Hanse towns: hence the greater part of the vast and profitable trade, which was lost to Antwerp, centered necessarily in Holland, where the manufacturers from Brabant were cordially received." This appears a satisfactory explanation why the English, in 1668, were so much inferior to the Dutch in the manufacture of fine cloth.

In the year 1660, however, our manufacturers began to be aware of the superiority of Spanish wool, and to mix it with the best English, probably in what were called medleys or mixture-cloths, or else employing the English wool for warp, and covering it with weft of Spanish wool. The best Spanish wool was then 4*s.* and the second sort 3*s.* per pound, and the best English 1*s.* 6*d.* per pound.

It is deserving of notice, that, in the latter period of the Commonwealth, our trade is said to have greatly revived, but to have suffered a miserable depression almost immediately after the restoration of Charles II. In a letter of M. Downing of the Hague to the president of the council in London, 1660, printed in Thurloe's State Papers, vol. vii. p. 848. it is stated, that great quantities of wool were brought secretly from England to Holland; and he adds, that the Dutch had at that time got in a great measure the manufacture of fine cloth, and would probably, with Silesia, engross also the manufacture of coarse cloth, and leave England nothing but its native wool to export.

In the year 1662, great complaints were made against the merchant adventurers for their neglect of the cloth trade; in reply to which they said, that the demand for English cloths failed in the foreign markets, the white clothing trade having abated from 100,000 cloths annually to 11,000. In the year 1663 our whole exports were only about two millions, and our imports four, leaving a balance of two millions against this country. It is, however, deserving notice, that the number of wardens for the inspection of stuffs at Norwich being too few, they were at this time increased from five to eight. A letter on the state of trade, published in 1667, says, clothing-wools were so much fallen at that time, that the best Spanish was sold at 2*s.* 2*d.* per pound, and English at 8*d.* per pound. The writer ascribes the fall in the price of English wool to our wearing so much Spanish cloth, a great part not manufactured by ourselves, as Dutch blacks; but it is obvious, from the price of Spanish wool, that the low price of clothing-wools at that time depended on a more general cause, affecting all manufacturing countries. To relieve the cloth trade from the great depression under which it laboured between the years 1660 and 1678, various schemes were devised. Among others, the mayor and common council of London passed an act "for the regulation of Blackwell-hall, Leaden-hall, and Welsh-hall, (the three public markets for cloth in London,) and for preventing foreigners buying and selling!" By foreigners are understood all persons not free of the city of London. This act, a most singular monument of the ignorance or selfishness of its authors, prohibits the sale of all woollen cloths sent to London, except at the above halls, where certain duties were to be paid upon them, and from whence they could not be removed for three weeks, unless they were sold in the meantime to some draper, or other freeman of the city. The hall-keepers were to attend strictly at the halls, and

WOOLLEN MANUFACTURE.

turn out all foreigners and aliens coming to purchase cloth; and every freeman of the city who should introduce a purchaser into the halls not free of the city should forfeit, for the first offence, five pounds,—for the second, ten,—and for the third, fifteen pounds! Thus, in those days, turning purchasers out of the public markets, and securing the sale to a certain class of buyers, was considered an act for the benefit of the public.

The Irish had, a little before this time, commenced the manufacture of woollens and worsteds, which appears greatly to have alarmed the English manufacturers. The wools of Ireland had increased in quantity, in consequence of a tyrannical act passed a little before this period, to prevent the Irish from sending cattle to England, which obliged them to convert their grounds into sheep-pastures. They were, however, prohibited from exporting their wool to foreigners, it being made felony; and the exportation to England, in any other than a raw state, exposed it to confiscation. About the year 1640 some clothiers from the west of England established a woollen manufacture at Dublin, where it flourished a considerable time. About the same period, sixty families of manufacturers from Holland settled at Limerick: these were ruined by the wars which ensued. Other English clothiers settled at Cork and Kinfales; a few French manufacturers of druggets settled at Waterford; and a more considerable establishment of the cloth manufacture was formed at Clonmel, supported by the capital of some London merchants, who had agents there. These establishments, though obviously inadequate to the supply of one-fourth part of the population of Ireland, excited great jealousy in the English manufacturers; and during the great depression of the woollen trade between the years 1660 and 1668, a part of this distress was ascribed to the rivalry of the Irish clothiers. The English farmers, at the same time, ascribed the low price of wools to the great importations of wools from Ireland; and the merchants ascribed the failure of the foreign demand for cloth to the clandestine exportation of English and Irish wools.

Sir William Petty, in the year 1672, estimates the sheep in Ireland at four millions, and the weight of each fleece at two pounds. The latter, however, is obviously not more than half the true average weight of the fleece, and the number is supposed by some to be below what it was a few years afterwards. If the number of sheep be correct, and taking the fleece of each at four pounds, this would make the total amount of Irish wools only 66,000 packs, of which three-fourths were consumed in Ireland.

The alarm and jealousy excited in England by the Irish woollen manufactures produced measures that almost compelled the Irish to export their wools clandestinely to the continent. An act was passed in the year 1699 prohibiting the exportation of woollen manufactures from Ireland, except to a few parts in England and Wales, where the duties imposed amounted to a total prohibition. Various addresses have been presented to the king and both houses of parliament, "beseeching his majesty to take effectual measures to prevent the growth of the woollen manufactures in Ireland." The Irish parliament was influenced to impose a duty in the same year of four shillings in the pound on their own manufactures when exported. These unjust proceedings were intended to annihilate the export trade for Irish woollens; and, in consequence, their wool and worsted yarn that was not consumed at home were sent to England, or to the continent clandestinely. The first four years after the destruction of their manufactures, these exports to England were as follow:

	Stone of Wool, 18lbs. per Stone.	Stone of Yarn, 18lbs.	Total of Wool and Yarn.
1700	336,292	26,617	362,909
1701	300,812	23,390	326,202
1702	315,473	43,648	359,121
1703	360,862	36,873	397,735

The average annual amount of wool and yarn, as above, may be stated at thirty thousand packs. But after this period the exports to England declined, owing no doubt to the clandestine exportation of wool to the continent, for which the numerous creeks and harbours offered such facility.

In 1711, and the three following years, the quantity exported to England was as under:

	Wool.	Yarn.	Total.
1711	310,136	52,273	365,409
1712	263,946	60,108	324,054
1713	171,871	68,548	240,409
1714	147,153	58,147	205,800

A few years after this, the decline was still more considerable in the amount of wool exported, but that of yarn continued to increase a little:

1726	51,371	87,261	138,632
1727	58,182	72,047	130,229
1728	49,784	80,428	130,212
1729	38,667	91,854	130,521

A further encouragement to clandestine importation was given by an impolitic duty of 2s. 4d. per stone on wool sent to England, which, as the average price did not exceed 6s. 6d., was full thirty per cent. on the first cost. It will be seen subsequently, that the woollen manufactures of England were all this time progressively increasing, so that the decline in the imports of wool from Ireland were not occasioned by a declension of trade; the Irish had found other markets for their wool.

From a work entitled "A New Discourse of Trade," by Sir Joshua Child, supposed to have been published about the year 1667, we learn several important particulars respecting the woollen trade. "Though our vent for fine cloths and stuffs to Turkey, Italy, Spain, and Portugal, were, he says, declined, yet we retained a considerable part, principally because the wool of which our middling coarse cloths are made is our own, and consequently cheaper to us than the Dutch can steal it from us." In another part he judiciously observes, that the acts for regulating manufactures, resolve themselves at last into a tax on the commodity, without respect to the goodness of it, as most notoriously appears in the business of aulnager, which doubtless our predecessors intended for a scrutiny into the goodness of the cloth; and to that purpose a seal was invented as a signal, that the commodity was made according to the statute; which seal, it is said, may now be bought by thousands, and put upon what the buyers please. Sir Joshua Child admits that wool was eminently the foundation of English riches, and that all possible means should be used to keep it within the realm; but the only efficacious measures to effect it are not penal statutes, but encouragement to trade. The impediments at that time he states to be, 1st, The high rate of interest; 2d, Want of hands, which an act of naturalization would cure; 3d, Compulsion (persecution) in matters of religion. For he adds, "while our neighbours the Dutch have money at lower interest and more hands, by reason of general liberty of conscience, with other free privileges, both to natives and foreigners, there is no question but they will be able to give a better price for our wool than we can afford ourselves, and they that can give the best price for a commodity shall never fail to have it by one means or another, notwithstanding the opposition

WOOLLEN MANUFACTURE.

opposition of any laws by sea or land; of such, force, subtilty, and violence, is the general course of trade."

The same enlightened writer appears to have been the first Englishman who saw the injustice, absurdity, and impolicy of the numerous restrictions by which the manufacturers were obliged to make cloths of certain weights and lengths, to keep only a certain quantity of looms, or to prohibit dyers, fullers, &c. from carrying on other branches of the trade. "It would be (he justly observed) for the advantage of the trade of England, to leave all men at liberty to make what cloth and stuffs they please, how they will, when and where they will, and of any lengths or sizes."

One of the principal causes of the decay of our woollen manufactures Sir Joshua Child might not think it prudent to state. This was the encouragement given to the consumption of French cloths and woollens in England, together with the total prohibition of English goods imported into France, or the imposition of duties which amounted to a prohibition. The French, under the administration of Colbert, had been extending and improving every branch of the woollen manufacture, and were become our great rivals in foreign markets, as well as at home. In the year 1678, acts were passed, the 29th and 30th of Charles II., prohibiting the importation of French commodities for three years. From this time trade began gradually to revive, and would have greatly increased, had not political causes operated as a check to our prosperity.

The improvements introduced in the manufacture of fine cloths by Brewer in 1668, and the more extensive consumption of Spanish wool, enabled us to oppose, with some success, the rivalry of the French.

After the accession of William, our manufacturers, who were warmly attached to the cause of religious liberty, being the greater part Protestant dissenters, were animated to uncommon exertions in the restoration of their trade. This is evident from the state of our exports in the following year after the revolution in 1689, when they amounted to near seven millions, of which the woollens were nearly three millions. This is the largest amount till the year 1715. A short time after the revolution, about the close of the century, our writers on Political Arithmetic, Mr. King and Dr. Davenant, give the following estimate of our national wealth, including wool, &c.:

	£
The annual income of England, of which the	
people subsist - - - - -	43,000,000
Yearly rent of land - - - - -	10,000,000
Value of wool yearly shorn - - - - -	2,000,000
Woollen manufacture of England - - - - -	8,000,000
Woollen manufactures exported - - - - -	2,000,000

From this period, the woollen trade of England kept progressively increasing, though subject to some fluctuations. In the following years the amount exported were as under:

		£
1718	value of woollens exported	2,673,696
1719	- - - - -	2,730,297
1720	- - - - -	3,059,049
1721	- - - - -	2,903,310
1722	- - - - -	3,384,842

About the year 1722, the plague at Marfeilles, by preventing the exportation of French woollens, increased the demand for English manufactures considerably. In the year 1737, the woollen exports amounted to 4,158,643^l.; and it is remarkable, that at that period the price of wool was uncommonly low.

The yearly medium value of woollen exports,	£
from 1739 to 1748, or to the peace of Aix-la-Chapelle, was - - - - -	3,327,057
Yearly medium of woollen exports, from 1749 to 1753, was - - - - -	4,189,195

From this time to the period of the American war in 1775, the woollen manufactures, and particularly the worsted, still continued to increase, with occasional checks. The quantity of long combing-wools grown in England had given to the manufacturers of worsted goods a decided advantage over those of France, though the ingenuity of the latter in the manufacture of les petites draperies, as the worsted goods are called, was greatly superior to what our own workmen had ever shewn. The demand for worsted goods at home, for tammies and stuffs, which were the general dresses of females before the year 1775, was very great; besides which, we supplied with worsted goods many of the southern parts of Europe, and particularly Spain and Portugal, for the use of their South American colonies, and for the dresses of the clergy, monks, and nuns, which form no inconsiderable part of the population in those countries. About the year 1775, the introduction of Arkwright's inventions for spinning, carding, &c. into the cotton trade, produced a great change in the article of female dresses in England, stuffs and tammies being supplanted by cotton goods, which were become extremely cheap. The failure of the foreign trade also greatly affected our manufacturers, both woollens and worsteds. The price of English wool at the latter end of the American war was lower than it had been in any period of our history, when money was of much higher relative value. A tod of 28lbs. of the best Lincolnshire wool for combing was not worth more than nine shillings, and the inferior kinds six shillings, or about three-pence and four-pence *per* pound. From the time of Elizabeth to the middle of the last century, scarcely any alteration or improvements had taken place in the processes of manufacture, either in woollen or worsted, beyond the variation of colours or patterns, to suit the fashion of the day. The ingenious mechanical inventions of Arkwright, applied to the spinning and carding of cotton, were soon after modified, and applied to the woollen and worsted trade, and produced an entire revolution in some of the seats of their manufacture. Before that period, the manufacture of heavy woollens and coarse worsted goods had been gradually concentrating into Yorkshire and Lancashire, where the cheapness of living, the active industry of the inhabitants, and, above all, the cheapness and abundance of coal, gave the manufacturers a decided advantage over those in the midland and western counties. The following table, shewing the amount of broad and narrow cloths made in the West Riding of Yorkshire, will prove the fact most decisively. It may be proper to remark, that eighty years since, about 1738, when our woollen exports exceeded four millions sterling, the total number of pieces of broad and narrow cloth made in Yorkshire was only fifty-six thousand nine hundred. At present our woollen exports are only about double what they then were; but the number of cloths manufactured in Yorkshire is not less than four hundred and ninety thousand pieces, or eight times more than the quantity made at the period above referred to. It must be remarked also, that this account does not include the cloth manufactured in Lancashire, and the borders of Cheshire adjoining Yorkshire, nor the blankets, serges, baizes, flannels, cassimeres, tolinets, carpets, rugs, worsted goods, or any other description of woollens or worsteds, except plain and narrow broad-cloths. The total amount of these different woollen articles exceed, we believe, in weight, if not in value, that of the woollen cloths.

WOOLLEN MANUFACTURE.

An Account of the Number of Broad Cloths, milled at the several Fulling Mills in the West Riding of the County of York, from the 24th of June, 1725, (the Commencement of the Act,) to the 12th of March, 1726, and thence annually, distinguishing each Year; and of the Narrow Cloths, from the 1st of August, 1737, (the Commencement of the Act) to the 20th of January, 1738, and thence annually, distinguishing each Year; likewise the Number of Yards in Length, made each Year, from Easter Sessions, 1768.

WOOLLEN MANUFACTURE.

In the table that will be afterwards given, it will be seen that the quantity of yards of different woollen articles exported, which are not included with cloths, greatly exceeds that of broad and narrow cloths. Taking this as a standard, it would appear that the cloth returned at the fulling-mills in the West Riding of Yorkshire is not more than one-third of the total quantity of woollens and worsteds of every description made in the West Riding of Yorkshire, and the borders of Cheshire and Lancashire. Now to make the quantity of broad and narrow cloth given in the returns of the West Riding, would require about one hundred and ten thousand packs: we may therefore state the annual consumption of wool in these districts to be from two hundred and fifty to three hundred thousand packs of 240 pounds each; and we may further state the amount consumed in these districts to exceed that of all the other parts of England and Wales collectively by one-third, including hosiery and all other articles made of wool. This will make the total amount of wool manufactured in England to be nearly what we have before estimated, or five hundred thousand packs.

The number of persons immediately employed in the various branches of the woollen manufacture in England was stated, in the year 1800, to be 1,500,000, and that the trade directly and collaterally employed double the above number. This was asserted in the speech of Mr. Law, now lord Ellenborough, in the house of lords, as council for the petitioners against the export of wool to Ireland. But we apprehend that the statement greatly exceeds the actual number employed in this trade, including their families.

The amount of the population of the West Riding of Yorkshire is nearly ascertained, and perhaps two-thirds of the whole may be engaged in the woollen manufacture, including the families of the persons employed. If we state these to be 340,000, exclusive of the woollen manufacturers in Cheshire and Lancashire, we shall certainly not under-rate them. A large part of the West Riding being agricultural solely, and in the manufacturing districts cutlery, as at Sheffield, and cottons in the more western parts, employ no considerable portion of the people. If then we take 340,000 as the amount of persons, with their families, engaged in the woollen trade in the West Riding, exclusive of Lancashire and Cheshire, and if we suppose that they are one-third of the total number of persons employed in the same manufacture in England, it will make the whole rather exceed 1,000,000 of manufacturers, including their families, which we apprehend is not far from the true estimate. We shall, however, give the precise words of Mr. Law's speech in the house of lords on the above occasion, the object of which, it must be recollected, was to enhance the importance of the woollen manufacture. "In order to give your lordships some idea of its magnitude, I may venture to state, that there are no less than 1,500,000 persons who are immediately concerned in the operative branches of this vast manufacture; and if what Dr. Campbell states in his 'Political Survey of the Kingdom' be true, that from the wool-grower to the consumer a piece of broad-cloth passes through 100 different hands, and that there are nearly the same number of hands dependent on the woollen manufacture, though not actually concerned in it, I may assume that the trade directly and collaterally employs double the above number of hands, or 3,000,000. If we estimate the magnitude of this question (the export of wool) according

to the number of persons interested in it, it goes to nearly one-third of the entire population of this kingdom, estimating that population at what is generally reckoned, namely between 9 and 10,000,000." Though the woollen manufactures of England have considerably increased within the last fifty years, we do not apprehend the number of hands employed is greater than before the introduction of mechanical inventions for carding, spinning, and combing. The working up of one pack of wool, particularly of combing-wool, formerly employed a great number of hands, and was divided into small portions, to be spun in the houses of cottagers in remote districts. This afforded employment to the wives and families of labourers who were engaged in agriculture; but so much time was occupied in taking out and collecting in the work, that at the period we refer to, few, if any, of the master manufacturers in Yorkshire consumed more than one pack of wool *per week* in their trade. At present there are numerous manufacturers in Yorkshire and Lancashire, who consume from twenty to fifty packs of wool *per week*.

The cotton manufacture, which may be regarded as of recent date, has employed the population that would otherwise have been thrown out of work in the woollen trade since the introduction of machinery, and has prevented any inconvenience of this kind from being felt at present in Yorkshire. We may, however, observe, that many branches of the woollen and worsted trade have been gradually retiring from the south of England, and concentrating in the West Riding of Yorkshire and in Lancashire. These districts were the first to introduce mechanical improvements into the woollen manufacture, and thus gained a decided advantage over the more ancient seats of the woollen trade. For several years afterwards the effects were felt in the manufacturing districts in the west of England, and great distresses from want of due employment for the labouring classes was the consequence.

At present all kinds of machinery that have hitherto been applied to wool are extensively employed in the west of England, and the manufacture of superfine cloth is in a flourishing state in the counties of Gloucestershire, Somersetshire, and Wiltshire, all ancient seats of the clothing trade. The manufacture of broad-cloth in other parts of the south and west of England is not carried on to any great extent. The manufacture of flannels, serges, baizes, &c. though branches of the woollen manufacture, are distinct from the cloth trade, and seldom carried on in the same district.

The export of woollen goods of all kinds from England, in the year 1815, amounted in declared value to ten millions one hundred and ninety-eight thousand pounds. This was rather an extraordinary quantity; and in the following year the exports fell under nine millions, which may be taken as the regular annual amount of woollen exports at present.

The following table gives the amount of different kinds of woollens exported, with their value, and the places to which they were sent in the year 1816; a year in which our foreign trade was considered as in a declining state. It may be worthy of remark, that though our woollen exports scarcely reached eight millions and a half, the amount taken by the United States of America in that year exceeded three millions; a fact which proves the vast importance of the American market to our manufacturers.

WOOLLEN MANUFACTURE.

If we state the amount of woollen goods exported to be about one-third of our own consumption, or from one-third to one-fourth, which is probably more correct, this would make the total value of manufactured woollens to exceed thirty millions annually. Of the woollen goods exported, the quantity consumed on the European continent scarcely exceeds three millions sterling in value, and a great part of that amount given in the preceding account was for army cloth. Hence it appears, that a very small proportion of the general population of Europe is indebted to this country for its woollens, including under the term both woollen and worsted goods. The increased demand for woollens of every description in England arises partly from the increase of population, but more from the increasing demand for articles of luxury or convenience. In the middle of the last century, carpets were scarcely to be seen in the country, except in the houses of the nobility; at present almost every house in England, except those of cottagers and the labouring classes, has carpets spread in some of the rooms. The consumption of worsted yarn in articles of furniture, and in the linings of carriages, and what is called horse millinery, is very great; add to which the people of England are better dressed than they were formerly. We may from all these causes state, that the home consumption of woollens, in proportion to our population, is double that of any other nation in Europe. To prove that we do not over-rate the proportion of woollens consumed at home, it may be sufficient to state, that the West Riding of Yorkshire alone manufactured, in the year 1817, nearly twice as many pieces of cloth as were exported in that year; but few woollen broad-cloths are made for exportation in the west of England, the manufactures there being principally fine and superfine cloth for home consumption, the value of which *per yard* on the average is much greater than that of the Yorkshire cloth. In the present state of Europe, we think it an encouraging circumstance to our woollen manufacturers, that so large a proportion of their goods are consumed at home, where the demand will remain certain; and again, that the United States of America take so considerable a part of our exports, as from the increasing population of these states, we may expect that the demand will be increasing for many centuries, and will soon exceed what it will be in the power of this country to supply.

In the year 1800, the woollen manufacturers of England were greatly alarmed at the liberty which was intended to be granted, of exporting wool to Ireland, and petitioned parliament against the measure. The grounds on which their alarms rested, were partly the preference given to the Irish, and partly the supposed facility that would be afforded to smuggling wool to the continent. Several manufacturers and wool-dealers from different parts of the kingdom were examined before the two houses of parliament; but neither in their evidence, nor in the speeches of the learned council, who were heard in support of the petitioners, can we trace any comprehensive or enlightened views of the subject. The objections urged against the export of wool were grounded principally on the practice of former reigns, particularly those of Edward III. and queen Elizabeth: but the facts we conceive were in opposition to the statements; for during the whole of the latter reign, in which our woollen manufactures were in a highly flourishing condition, the export of wool was freely admitted, on the payment of certain duties; and during the reign of Edward III., the prohibition to export wool under heavy penalties was confined to denizens and foreigners, in order to secure a larger amount of duties to the king, the former paying less duty on exports than natives; nor was it till the reign of Charles II. that the ex-

port of wool was strictly prohibited. All the former prohibitions were evadable by licences, which were readily granted for money. It is from this reign, therefore, we must date the prohibition to export wool, as forming an established law of the land; and it is not unworthy of remark, that immediately after this period, and to the time of the revolution in 1688, our woollen manufactures were in a very declining state, which proves that they had not derived much benefit from the measure. The policy of admitting the export of wool has been again recently agitated in parliament, and has renewed the alarm of the manufacturers. It is not by precedents drawn from former ages, but solely by the wisdom and justice of the measure, as applicable to one present condition, that a question of this kind should be determined. With respect to short or clothing wool, we believe that a permission to export it would not produce the least effect, as we already import these wools from almost every nation in Europe; it is not, therefore, probable, that foreigners would give a better price for them than our own manufacturers can afford. With long combing-wools, the case is somewhat different, as by the acknowledgment of the French themselves, these wools are wanted to mix with and improve their own. We apprehend, however, that as much is exported at present clandestinely in the form of worsted yarn, as the market may require, the free export of cotton yarn giving great facility for evading the penalty, by packing them together. The permission to export wool to Ireland, which was granted in 1800, has not been attended with any one of the fatal effects which our manufacturers anticipated; nor do we apprehend, that permitting the free export of wool under certain duties would be found to injure our own woollen trade.

In taking this view of the subject, which we trust is an impartial one, we readily admit that the permission to export wool, were it granted, would not be attended with any permanent benefit to the landed interest. A small pamphlet on the subject, recently published by John Maitland, esq., contains the following judicious observations:—"The manufacturer of our native wool claims from government the preservation of it for his use; for *by the statute law of the land, he is confined to its soil for the express purpose of working up the wool which grows upon it.* This wool cannot, therefore, upon any just or moral principle, be permitted to go out of the country in an unmanufactured state, without allowing the manufacturer to follow it, or without obliging the grower and exporter of it to maintain him and his children." This is so obviously just, that whenever the export of wool is admitted, we cannot any longer, as at present, prohibit the woollen manufacturers from emigrating and carrying their industry to the best market. "The wool," as Mr. Maitland elsewhere observes, "does not on an average compose more than one-sixth part of the value of the animal on which it grows; and the manufacturer, by obtaining this sixth part, at such a moderate rate as may enable him to sell his goods, when manufactured at a reasonable profit, insures to the owner of land a moral certainty of obtaining the full value for the remaining five-sixths, and receiving an ample price also for all the other productions of his ground." The truth of this observation we know to be fully proved in the Yorkshire markets. Whenever there is any considerable depression of the woollen trade, it is always attended with a decreased consumption of animal food, supplied principally from Lincolnshire, and the counties which produce the largest quantity of wool. Should the permission to export wool be attended with any effect in diminishing our own manufactures, the result would be highly injurious to the land-owner, who would then have to find new customers for his

WOOLLEN MANUFACTURE.

his general produce, and new associates to share with him the burden of taxation.

The prices of heavy combing-wool in Lincolnshire, Nottinghamshire, or Leicestershire, may be taken as the average price of this kind of wool over the whole kingdom, there being little variation in the value of this wool from different districts. The following table will shew what have been the prices for a great part of the last century :

Price *per* Tod of Lincolnshire Fleeces, the Tod weighing 28 lbs.

From the year 1744 to the year 1777, the prices, though occasionally fluctuating, continued much the same as in the preceding years, but we have not the means of ascertaining precisely what they were in each year. The following table will shew the prices of Nottinghamshire and Leicestershire heavy combing-wool, taken from the most authentic source. We consider the value of this wool to have been fully equal to that of Lincolnshire on each year.

The above were the average prices of the best lots ; the inferior ones might range from one to two shillings *per* tod under the prices here given. It may be observed, that the price of this kind of wool was lower towards the close of the American war, or about the year 1781 and 1782, than in any former or subsequent period of our history, if we take into consideration the relative value of money. At that time, the quantity of wool unfolded in the hands of the farmer was nearly equal to three years annual growth ; a quantity too large to have been consumed by our manufacturers, had not the introduction of machinery enabled them to work it up with much greater facility than formerly. The average weight of these fleeces may be stated at four or seven pounds each fleece to the tod of 28 pounds. Since the commencement of the present century, the price of this kind of wool, it will be seen from the above table, has been amply sufficient to remunerate the wool-growers ; and we confess we are utterly at a loss to discover on what grounds of sound policy or interest they would wish to make any change in the laws respecting the export of wool. With respect to short or clothing wools, any change in the existing laws would make no alteration whatever in the price ; for it is the extreme of prejudice to assert, that our native clothing fleeces are necessary to the foreign manufacturer, either to supply his demand or improve the quality of his own wool. We might with equal justice revive the absurd opinion, so confidently maintained a few years since, that the best Spanish wool would not make cloth without an admixture with that of England.

WOOLLEN-MANUFACTURE.

WOOLLEN Manufacture, Process of. In an early part of this work, under the article CLOTH, we have given a general view of the process of cloth-making, furnished by a principal manufacturer in the west of England. In the present article, we shall confine our account chiefly to those improvements in the processes which have since been introduced, and shall add a description of the machines which were only slightly noticed in the article CLOTH, and give references to the plates. The processes of the woollen manufacture may be classed under two heads; those by which wool is prepared for the weaver, and those by which the cloth is finished after it is taken out of the loom. The sorting of wool has already been referred to under the article WOOL. English wool is supposed to be sufficiently cleaned from pitch marks or other extraneous substances by the wool-sorter, and left by him in a proper state to commence the process of cloth-making. Spanish wool in the bale has generally some part of the pitch employed to mark the sheep still adhering to it, which must be carefully cut off. It was till recently the practice to beat the wool with rods, in order to shake out the dust and open the staples; but this is now principally done by an opening machine with long coarse teeth, called a devil, or wool-mill. Spanish wool is frequently so hardly pressed together in the bag, that it requires to be opened out by beating, to prepare it for the further processes.

In the west of England, wool is generally scoured before it is dyed or carded; but in Yorkshire this is seldom practiced on wool intended for white cloths, and among the smaller manufacturers who dye their own wool, it is frequently put into the dyeing-vat unscoured; a practice which injures the brightness of the colours, but which enables the manufacturer to make a greater weight of cloth with the same quantity of wool. There is also some saving of labour and expence; but this is more than counter-balanced by the increased quantity of oil *per* pack required for unscoured wool, which is at least one-third more than would be necessary if the wool were scoured. In the west of England, where the wool is scoured previously to its manufacture, the process is carried on with a degree of neatness and cleanliness, which form a perfect contrast with the horrid stench and disgusting filthiness of the woollen factories in Yorkshire. For fine cloths, olive-oil, called Gallipoli, from the part where it was supposed to be sent, is principally used; and for the coarser cloths rape-oil. Where attention to colour is not required in very coarse goods, fish-oil is sometimes employed; but if the latter remain in the wool or cloth, it turns it brown, undergoing a degree of fermentation injurious to the cloth, and which sometimes occasions spontaneous combustion. To lessen the expence of oil for coarse cloths, some manufacturers in Yorkshire make use of a mixture of soap and water with oil, which answers very well in moist weather, if the wool be immediately carded and spun; but if it remain some time unwashed, or the weather be very hot, the mixture evaporates. It has been attempted to work wool without any oil whatever, but without success. The use of oil is to cover the surface of the fibres, and enable them to slide easily over each other in carding or spinning. What we have before said of the structure of the surface of wool or hair, under the article WOOL, will suffice to shew the advantage that must result from oiling. The wool is sprinkled with oil as evenly as possible. In Yorkshire the proportion on fine wool is about six gallons *per* pack, and this is more equally distributed over it by the wool-mill, through which it passes previous to the process called scribbling. This process is a kind of coarse

carding, and is performed on a machine similar to that used for scribbling cotton, but larger, and with coarser cards, the principle being similar to that of the carding-machine, hereafter to be described. By this engine the longer fibres are broken down, and they are all laid straight and nearly parallel to each other. The wool leaves the roller of the scribbling-mill in one thin undivided sheet, and the more clear, even, and transparent it appears when held between the eye and the light, the more perfectly has the operation been performed. On the carding-engine, the operation is repeated on finer cards; but instead of leaving the machine in one continued sheet, it is finally divided into separate portions, which by a fluted roller are formed into separate round pieces about one inch in diameter, and two feet three inches in length. The fibres are now arranged so as more easily to slide over and twist round each other in the next process, which is a kind of coarse spinning called slubbing, performed with the slubbing-machine, which will be described. On this machine each of the rolls from the carding-machine are joined together, and drawn out into a loosely-twisted thread, and wound round a spindle, forming what is technically called a *slubbing*. These slubbings being taken to the spinning jenny, which will also be described, are twisted in an opposite direction, and drawn out into threads of yarn of the requisite length. For very fine yarn used in shawls, a machine called the mule is sometimes employed, nearly similar to the cotton mule (see *Manufacture of COTTON*), the slubbing passing through rollers which assist in drawing out the thread smaller and more regular. The yarn is now prepared for winding, sizing, warping, and weaving. (See CLOTH.) Since the article CLOTH was written, broad-cloth is almost universally woven by one person only in a loom, making use of the fly-shuttle. (See WEAVING.) The next process is scouring and burling, already described under the articles CLOTH and FULLING. The cloth is then sent to the fulling-mill; the finer kinds are prepared for fulling by a mixture of soap and water; in coarse kinds, fuller's-earth supplies the place of soap. (See FULLING-Mill, and a farther description at the end of the article.) The principle on which the felting depends has been described under the article WOOL. By the process of fulling, the cloth becomes shortened in length and breadth, and the fibres are incorporated and intimately united with each other. In the best manufactured cloths, this incorporation is so complete, that the separate threads can scarcely be distinguished, the bottom of the cloth appearing to form one even continuous substance. An improvement in this respect has recently been made at Leeds, by spinning the wool much softer and thicker than has usually been the practice, and uniting the threads in the fulling-mill, and then working the substance of the cloth down to a requisite degree of thinness by the gig-mill, hereafter to be described. At the end of the process, the face or surface of the cloth is much softer, and greatly superior in appearance to cloth manufactured in the common process. A pack of wool of 240 lbs. will make when milled about one hundred and twenty yards of mixed or coloured cloth from fifty to sixty inches in breadth, according to the quality and fineness of the wool. The process of raising, shearing, and pressing, have been mentioned under the article CLOTH, and will be more fully described when an account is given of the gig-mill and shearing-machine. The object of these processes is to cover the thread with a soft pile, consisting of the fibres of the wool, cut down to an even surface over the whole piece.

There are various kinds of woollen goods worked on the same principle as cloth, and made with both the warp and the weft

WOOLLEN MANUFACTURE.

west of carded wool, but which being unmilled, or finished in a different manner, receive different names. Blankets are manufactured on the card, but from wool that possesses a greater length of staple, and which therefore admits of a deeper pile, being raised on the surface. The yarn is spun thicker, and left as soft as possible, in order that it may form a full cover or pile. Fine blankets are made much flouter and heavier than coarse ones; they are both scoured in the mill, but are scarcely suffered to undergo the fulling process. Thick cloths with a long pile, called duffields, fearnoughts, and bear-skins, are manufactured on the same principle as blankets, but they are milled much thicker and dyed, and also raised to a deeper pile. Flannels and very light cloths, such as Bath coatings, are usually spun small, in proportion to the quality of the wool. In weaving plain cloths, the chain or warp is equally divided by the gears, one half of the threads being above and the other half below, and they cross each other every time the thread of the west is thrown through by the shuttle. In weaving kerseymeres or cassimeres, on the contrary, the warp is unequally divided, to produce what is called the twill, or twel, (see WEAVING,) one-third being always above and two-thirds below the shuttle as it passes. It is owing to this arrangement of the warp, that it forms a slanting or diagonal rib across the body of the cloth, which is the distinguishing character of this kind of woollens. See *DRAUGHT of Looms*.

Cassimeres are usually set in the loom from thirty-four to thirty-six inches wide, and milled to twenty-seven inches. Forty pounds of wool from the bag will make rather more than sixty yards of common milled fine cassimeres; the double milled ones make less in proportion to the degree of milling they receive.

Swandowns and toilinetts are made with a cotton warp; the west is woollen or worsted yarn of various colours, according to the patterns required. Woollen cords have also the warp of cotton and the west of woollen; they are woven and cut precisely in the same manner as cotton cords. See *FUSTIAN*.

Serges are made with the warp of worsted and the west of coarse woollen yarn, and are twilled. These goods have been for a very long time manufactured extensively in Devonshire, and are principally purchased by the East India company for the China trade.

Carpets have worsted warps and woollen wefts. See *CARPET and WEAVING*.

From the most remote period of the woollen manufacture until the latter end of the last century, or about the year 1780, very few, if any, mechanical improvements had been introduced into it. During the whole time the various processes were carried on nearly in the same manner, but with greater or less skill, and were employed upon materials more or less valuable. The carding and spinning of wool, and the weaving and finishing of cloth, in the early part of the reign of George III., were effected by the same machines as in the time of Edward III., which probably were similar to those of the ancient Romans, but more rude in their construction. In an art which had seen so many centuries roll on without any change, it did not appear possible to the manufacturer that any improvement could be effected; and had not the genius of Hargreaves and Arkwright changed entirely the modes of carding and spinning cotton, the woollen manufacture would probably have remained at this day what it was in the earliest ages of civilized society. That it would have been better for general society if it had so remained we readily admit; but after the improved modes of working cotton were discovered, this was impossible. The spinning jenny, which was the same as that employed in

the cotton manufacture, but somewhat larger, was introduced into Yorkshire from Lancashire about the year 1780, but did not become general till about three years afterwards. In the first jennies, not more than eighteen or twenty threads could be spun, and the mode of winding the thread upon the spindle was very imperfect. The carding was still effected by the hand, and the slubbing or roving was prepared on the common spinning-wheel. For some time considerable difficulty was experienced in carding by machinery, particularly in clearing the wool from the card; and a slight change in the construction of the machine was found necessary to prepare the wool for the slubbing-billy, of which an account will be given in the description of the carding-machine. Soon after this, the carding and spinning of wool and yarn by machinery became general through the manufacturing districts of the West Riding of Yorkshire, and large mills were erected, in which the carding and scribbling machines were turned by a water-wheel, and the roving or slubbing performed on the billy. The wool carded at these mills was sent to the smaller manufacturers in the state of slubbing, and the farther process of spinning was effected on jennies in their own premises. Before the year 1787, the old processes of carding by the hand, and spinning on the wheel, were entirely discontinued in Yorkshire; but it was some years after before the new processes were generally introduced in the west of England, and thus, as we have before stated, the woollen trade became more concentrated in Yorkshire, where cloths could be manufactured at less expence. About this time, machinery began to be applied to the combing and spinning of long combing-wool, to make worsted yarn. See *WORSTED Spinning*.

In consequence of the great increase of trade in Yorkshire, it was found difficult to obtain situations for mills to be turned by water, and the application of the steam-engine to woollen machinery became very general. The abundance of fuel was highly advantageous to the Yorkshire manufacturer; and it was found to be equally cheap to work the machines by steam as by water, where any considerable rent was paid for the water. The motion of the improved steam-engine was also rendered as regular as a water-wheel, and the great inconvenience and loss from the interruption of the works by frosts or continued droughts were thereby avoided.

The smaller manufacturers in Yorkshire were at first benefited by the introduction of machinery, but in a little time large capitalists began to engage in the woollen trade, and performing all the processes with their own machinery, they were enabled to work cheaper and undersell the smaller makers. The facility also with which wool could now be worked up kept the markets always well stocked with goods, and prevented the manufacturers from taking the advantage of a temporary scarcity or a brisk demand, which they had formerly done, an overstocked market always reducing the profits.

Soon after the year 1800, the number of small manufacturers began rapidly to decrease many of them, being ruined by the change which had taken place, and compelled to become workmen in the factories of the large capitalists.

The gig-mill and the shearing-machine were not introduced into Yorkshire until they had been several years employed in the west of England, owing to the resistance made to them by the working cloth-dressers or croppers in the north.

The manufacture of worsted is properly a branch of the woollen manufacture, and noticed as such in our history of its progress in England; yet the mode of manufacture, both in preparing the worsted yarn and finishing the goods, being entirely

entirely different from woollens made of carded wool, and part of it being applied to hosiery, we refer, for a further account of it, to the articles *WORSTED Manufacture*, and *WORSTED Spinning*.

Description of the Machines employed in the Woollen Manufacture.—The *wool-mill*, or *willy*, is the first machine which is employed on the raw wool to open and disentangle the close matting, in which the wool comes from the wool-stapler. It is also used for clearing the dyed wool from the dye stuff, and again for mixing different parcels of wool together; also for incorporating the oil with the wool.

The wool-mill used in Yorkshire consists of a cylindrical drum, about three feet long and two feet and a half diameter, which is made to revolve near three hundred times *per* minute. Its circumference is furnished with teeth or spikes, and immediately above it five small rollers are placed, which are also furnished with similar teeth. The teeth of the rollers and those of the drum intersect each other when they all turn round; and the teeth of the five small rollers also intersect each other. The cylinder and rollers are inclosed in a box or case, which is closed on all sides, except a door in front, which turns down, the hinges being at the lower side. When this door is shut up it stands in a perpendicular plane, very near to the teeth of the drum; when the door is opened, or turned down into the horizontal position, the wool is laid upon it, about one pound weight at once, and the door being closed the wool is brought within reach of the teeth of the cylinder, which take the wool and carry it upwards, so as to work it between the teeth of the cylinder and those of the five rollers placed over it. This effects the opening of the wool, and breaks the fibres if the staple is too long: it also separates the matted fibres. In about three seconds, the pound of wool is generally sufficiently worked, during which time the cylinder has made about fifteen turns. The lower part of the case in which the cylinder revolves is a grating of wooden rods, through which the dirt and dust escape. The cylinder is fitted very close to this grating, so that the wool cannot escape from the cylinder, but is carried round in it, and is thus repeatedly submitted to the action between the teeth of the cylinder and those of the rollers. When it is judged that the wool is sufficiently worked, the door is opened again, and the centrifugal force throws out the wool in an instant; a fresh charge is then laid upon the door, and shut up in the machine. A preferable mode is to have two doors on opposite sides of the case; one to put in the raw wool, and the other for the finished wool to come out at.

The wool for coarse goods is passed several times through the wool-mill; first, to break the mats of the raw wool and render it light; then a second time after it is dyed; a third time to mix the different sorts together; and lastly, after the wool is oiled, it is passed a fourth time through the wool-mill, with a view to incorporate the oil well with the fibres of the wool.

Scribbling-Machine.—This is the first stage of carding. The operation tends to disentangle the fibres which were before closely entangled, and draw them out separately, so as to render the wool light and flaky. The scribbling-machine is very similar to the carding-machine, having a large cylinder or drum, which is covered on the surface with sheets of leather stuck full of projecting wire-teeth, called card-wires. The teeth are so close together as to cover the whole surface of the cylinder, like the bristles of a brush. This cylinder is turned rapidly round by the machinery, and the wool is regularly and slowly supplied by feeding machinery to its teeth, which take it up, and the cylinder, as it were, clothes itself with wool. This wool is carded or worked by

the teeth of several other smaller cylinders, called workers and clearers, which are fixed around the great cylinder in pairs. The teeth of the workers take the wool from the great cylinder, and give it to the clearers, which return it again to the great cylinder. It is then transferred to another worker, and by its clearer is given back to the great cylinder, and so on. It is by the repeated transferring of the wool from one cylinder to another, that the chief action of scribbling or carding is performed. The teeth of the different cylinders do not actually touch each other, but they work so near together, that the fibres of the wool which the teeth of one card contains are caught by the teeth of the other card, and drawn out a very few at a time. This action tends to separate the fibres, and renders the wool light and open, and also distributes the wool with great evenness over the surfaces of the cylinders. After the wool has passed between three or four pairs of workers and clearers, it is taken up by a cylinder, called the doffer, which is smaller than the great cylinder, and turns round very slowly. The wool is stripped off from this doffer by a steel comb, which is situated parallel to the axis of the doffer, and is moved rapidly up and down by a crank through a small space. In ascending, the comb does not touch the doffer; but when the comb makes its down stroke, it comes in contact with the teeth of the cards, and combs out almost all the wool they contain. As the doffer turns round very slowly, and the comb acts at small intervals, the successive portions of wool which it combs or strips off, hang together in a continued fleece or web of a very thin texture, which hangs down from the doffer, and is received in a basket.

The wool in this state is said to be scribbled, but the fibres are not yet sufficiently combed out or separated; for on examination of the scribbled wool, many small knots and films of wool are found, which are still closely entangled. The scribbling is therefore repeated twice or three times, and then the wool undergoes another operation, which is called carding, but which is very nearly the same as the scribbling, only the wool is formed into small cylindrical rolls, which are the first rudiments of a thread.

We have thought it needless to give a drawing of a scribbling-machine, as it may be readily conceived from the following description of the carding machine.

Carding-Machine. (See Plate IV. *Woollen Manufacture*.)—A is the wood frame of the machine, but the best machines have cast-iron frames; C C is the outside of the large cylinder, which is about thirty inches diameter, and twenty-six inches wide: its axis is supported on bearings at each side of the frame, and it is put in motion by an endless strap applied upon a pulley at one end of its axis, which pulley cannot be seen in the figure. The cylinder revolves about 100 times *per* minute. B is an arch of wood to receive screws, which support the six small cylinders marked 2 a and 2; these are the workers and clearers. The workers 2 a are larger, and turn slower than the clearers 2; each worker is acted upon by its clearer, and both worker and clearer act against the cards of the great cylinder.

The raw wool is spread evenly upon the feeding-cloth 5, at one end of the machine: it is an endless sheet stretched over two rollers, one of which has a cog-wheel G upon the end of its axis, and receives motion from a pinion situated behind the pulley F. This pulley is turned by an endless cord passing round a pulley n, fixed upon the cog-wheel E, which is turned by a pinion 8 on the end of the axis of the great cylinder. The wool which is spread on the cloth 5 is taken off, between a pair of feeding-rollers, which are clothed with cards laid on in spiral fillets. These rollers cannot be seen, being within the frame; they are about 2½ inches

WOOLLEN MANUFACTURE.

inches diameter, and are turned round by toothed pinions on the axis of the cloth-roller, so as to move rather quicker than the feeding-cloth. The feeding-rollers give the wool to a cylinder 4 *a*, called the carrier, which is about nine inches diameter. The carrier works against the cylinder C; but as its surface moves more slowly than the surface of the cylinder, the wool contained in the teeth of the carrier is taken up by the cylinder. The carding-machine represented in our plate is shewn with a cylinder 3, beneath the carrier; this is not used in the present machines, but the feeding-rollers give the wool at once to the carrier 4 *a*.

That part of the cylinder which is adjacent to the carrier moves upwards, so as to carry up the wool it has taken from the carrier, and give it to the workers 2 *a* and clearers 2. The surfaces of the workers 2 *a* move in the same direction as the surface of the great cylinder, but they turn slowly, being put in motion by the chain 9, which passes over wheels at the ends of all the three workers. These wheels have cogs or teeth to enter into the links of the chain, and prevent it from slipping; the chain passes beneath a wheel fixed on the axis of the cog-wheel E, but within the frame. The wheel E is turned by a pinion 8, fixed on the extremity of the axis of the great cylinder; and the proportions are such, that the workers 2 *a* revolve once to about four turns of the great cylinder, and the workers being about 6½ inches diameter, whilst the cylinder is 30 inches diameter, the surface of the cylinder moves about 18½ times as fast as the surfaces of the workers.

The small rollers 2, called clearers, are placed so as to card the wool on the workers, and on the great cylinder also. The clearers are turned round very quickly, and take the wool from the workers, but their surfaces do not move so fast as the surface of the cylinder. Thus the strap 13 passes over a wheel of about 8½ inches diameter, fixed on the extremity of the axis of each clearer; this strap is put in motion by a wheel of about 22 inches diameter, fixed on the axis of the great cylinder; therefore, the clearers turn about 2½ times to one of the great cylinder; but as they are only 3¼ inches diameter, and the great cylinder is 30 inches diameter, the surface of the cylinder moves near 3½ times as fast as that of the clearer. The carrier 4 *a* is turned by the same strap 13; but being larger than the clearers, its surface moves much quicker, so that the cylinder's surface moves only about once and a half as fast as the carrier's surface.

The strap 13 also turns a cylinder 2, at the right-hand end of the machine, called the fly: its surface moves the same way as the surface of the cylinder, but moves nearly once and a half as fast; the pulley at the end of the fly being only 4¼ inches diameter, and the fly itself nine inches. The fly is not placed so close to the cylinder as to take the wool away therefrom, but is intended to raise and loosen it in the cards of the cylinder, so that the cylinder 4 beneath it, called the doffer, can take off the wool more readily. This doffer is 14 inches diameter, and is covered with separate sheets of card-wire, each about 4 inches wide, leaving vacant spaces between them parallel to the axis of the cylinder. The doffer moves round very slowly, its surface moving only $\frac{1}{10}$ of the velocity of the surface of the cylinder: it is turned by a band from a pulley on the axis of the roller D, which we shall next describe.

The comb which works against the surface of the doffer, and strips off the wool from it, cannot be seen in the drawing. The comb is supported by two upright rods, screwed to it one at each end; the upper ends of these rods are guided by two horizontal levers, and the lower ends are jointed to two small cranks formed on an horizontal axis, which is situated at the lower part of the frame near the

ground, and put in rapid motion by a strap, from a pulley at the bottom of the frame beneath the great cylinder. This pulley has a smaller one fixed on the extreme end of its axis, and receives its motion from the same strap 13, which turns the clearers. Every revolution of the cranks causes the comb to rise and fall about two inches; and when the comb descends, the teeth on its edge act against the cards, on the surface of the doffer 4, so as to take out the wool from them. This wool is separated in a continued sheet or film, because the strokes of the comb succeed each other very quickly, and the doffer turns round slowly; but owing to the vacant spaces between the cards on the doffer, this film only continues for a width of about four inches, and is then discontinued until the vacant space on the doffer has passed by the comb, which then acts again to strip off the wool, and so on: hence the wool is drawn off from the machine in a carded state, in small and very delicate films or webs of about 4 inches wide, and 27 or 28 inches long, which is the length of the doffer.

These detached portions of wool are next rolled up so as to form small cylindrical rolls, which is done by what is called the roller-bowl D: it is a cylinder of wood, with shallow flutes upon its surface, parallel to its axis; it is turned round slowly by a pulley H on the end of its axis, and an endless band, 14, which passes round a pulley I, fixed on the wheel E. The lower part of the roller-bowl, D, is inclosed within a hollow cylinder of wood, called the shell; it encompasses the lower half, being fixed beneath the revolving cylinder; the shell is fluted within side, but does not touch the bowl, leaving a small interval between the two. The portions of wool, as they are stripped or combed off from the doffer, fall down over the edge of the shell, which for that purpose is situated close to the doffer, at that part of its circumference where the comb works: by this means, the wool which is stripped off falls down into the space between the shell and the roller-bowl; and when the portion of wool is completely detached and drops off, the motion of the bowl within its shell rolls the wool between them with a rolling motion, which forms the wool into a very round and straight cylindrical roll, called a carding, when these cardings drop out from between the roller-bowl and its shell; they fall upon a flat table, *a a*, as shewn at 7 7 7. This table is covered with an endless cloth, which is stretched over two horizontal rollers; one of these rollers has a cross, marked 16, 16, fixed on the end of its axis; the arms of the cross are seized by a cranked lever, 15, which is fixed to the axis of the roller-bowl, and at every revolution the cross 16 is turned round one-fourth: this moves the endless cloth forwards, and carries the cardings away in the manner shewn at 7 7 7, as fast as they drop out from the shell, and from this table they are carried away to the slubbing-machine, or billy.

In most modern machines the latter movement is altered, the endless cloth being kept in a continual and slow motion by an endless band passing round a small pulley fixed to the pulley H, and a larger pulley fixed in place of the cross 16.

In some old carding-engines many of the motions were performed by toothed wheels and pinions; but of late years all the parts are moved by bands or straps, which produce a much more equable and steady movement. The large cylinders are generally made by placing two or more wheels of cast iron on one axle, the circumference of the wheels being cased with wood, which is attached to them by screws or rivets. The smaller rollers are formed in a similar manner on wooden disks, but all are made hollow, to avoid warping, which would render the action of the cards irregular and uncertain.

WOOLLEN MANUFACTURE.

We must now return to the scribbling-machine: it is the same as the carding-machine, except that the breadth of the cylinder is greater, and the teeth are coarser; there is no roller-bowl D, and the doffer 4 is completely covered with cards, without any breaks or intervals; hence the film of wool which is taken off is continuous, and is suffered to fall down into a basket.

Double Scriblers.—In Yorkshire it is common to employ double scriblers; that is, two of the machines combined together, and placed in one frame; there are two large cylinders, each surrounded with its workers and clearers, and doffer, as we have described, making in all seventeen small cylinders. The first great cylinder has a feeding-cloth and carrier, to supply the wool to the cylinder; but the second large cylinder is supplied with wool from the doffer of the first cylinder, which doffer serves in place of a carrier to the second; it therefore has no comb. The doffer of the second cylinder has a comb to take off the wool, which then falls into a basket.

This machine is said to save trouble of attendance, and does more work than two single machines. The usual practice is to pass the wool once through the double machine, and then once through a single machine. A double machine will scribble about a hundred weight of wool *per* day.

After the wool is scribbled it is weighed, and when it is taken to the carding-machine, a certain weight is spread over a certain length of the feeding-cloth, so as to supply the wool to the machine with perfect regularity. The proper weight which should be allowed is ascertained experimentally, according to the fineness of the thread which is required to be spun. The cardings are weighed from time to time, to ascertain if each one contains the proper quantity of wool.

The cardings produced by the united operations of scribbling and carding are composed of fibres of wool laid very lightly together with the least possible entanglement; they are very regular and even in size, and upon this circumstance the perfection of the spinning chiefly depends.

Slubbing-Machine, or Billy.—This performs the first process of spinning. It reduces the cardings, and draws them out in length; joins them together, and gives them a slight twist, in order to form a coarse and loose thread, called a slubbing or roving, which must be spun over again in the jenny, to make a thread fine enough for the loom.

This operation was formerly performed by hand on the common hand spinning-wheel, which is similar to that used for spinning wool, but of a smaller size. Machines were then contrived by which a number of slubbings could be drawn out together; but the aid of the hands was required for joining the rolls or cardings of wool together in succession, and for other purposes, which were found to take so much time, that very little, if any, saving of labour was effected by the use of such machines.

A perspective view of the slubbing-machine, now universally employed, is given in *Plate I. Woollen Manufacture*. A A is the wood frame of the machine; within this frame is a moveable carriage, D D, which runs upon the lower side-rails at a a, with wheels 1, 2, to make it move easily; and it is capable of running backwards and forwards in the frame from one end to the other. The carriage contains a number of perpendicular spindles, marked 3, 3, which are put in rapid motion by a long cylinder F, and a separate band from each spindle, which passes round a small pulley on the spindle. The cylinder F extends horizontally across the whole breadth of the carriage; it is made of tin plate, hollow like a tube, and covered with paper on the outside.

The spindles are placed in a frame, so as to stand nearly perpendicular, at about four inches from each other; their

lower extremities are sharp-pointed, and turn in sockets, and they are retained in their perpendicular position by a small collar of brass for each, which surrounds the spindle at about the middle of its length. The upper half of each spindle projects above the frame, and on the lower part the small pulley or whirl is fixed, to receive the band from the horizontal cylinder, which is about six inches in diameter, and a little longer than the row of spindles; it is placed before them with its centre at a lower position than the row of whirls. The cylinder receives motion by a pulley at one end, with an endless band from a wheel E, made like the large wheel used in spinning wool by hand, and of the same dimensions. The wheel is situated at the outside of the great frame of the machine, and its axis is supported by upright standards erected from the carriage D; the wheel is turned by the left-hand of the spinner, applied to a winch, which is plainly seen in the drawing, and gives motion to the cylinder F, which again turns all the spindles at once with a great velocity.

Each spindle receives a thread, or slubbing, which threads issue from beneath a roller, C C, at one end of the frame, and proceed to the row of spindles placed in the carriage, so that the slubbings are extended nearly in an horizontal direction. The spindles, by the motion of the carriage, are capable of advancing or retreating from the roller C, so as to extend any required length of slubbing.

The cardings of wool, which are to be spun into slubbings, are extended side by side upon an endless cloth, which is strained in an inclined position between two horizontal rollers, one marked B B, and the other cannot be seen. There is one carding for each spindle, and the number is usually from 50 to 80. C is a light wooden roller to bear upon the cardings which lie upon the cloth, and press slightly upon them by its weight. Immediately before this roller is a wooden rail G, and another beneath it, which is fixed horizontally across the frame: the cardings are conducted between these two rails, the upper of which is capable of rising; but when it falls by its weight, it holds the cardings fast between the two, and hence these rails are called the clasp; the upper moveable rail G of the clasp is guided between sliders, and a wire 7 descends from it to a lever 6. When the carriage D is wheeled close home to the end of the machine, a wheel 5 lifts up the end 6 of the lever; and this, by the wire 7, raises the upper rail G so as to open the clasp, and release all the cardings: in this state, if the carriage is wheeled or withdrawn back from the clasp, it will draw the cardings forward. There is a small catch which receives the upper rail G of the clasp, and bears it up from falling until the carriage has retreated a certain distance, and drawn out about eight inches length of the cardings; a stop on the carriage then comes against the catch and withdraws it; the upper rail of the clasp G then falls and holds the cardings fast, whilst the carriage continues to recede, and draw out or stretch that portion of each carding which is between the clasp and the spindle. All this time the wheel is turned to keep the spindles in motion, and give twist to the cardings in proportion as they are drawn out, by which means it is prevented from breaking; because as the carding diminishes in size, and increases in length, the increasing twist combines the fibres of the wool, so as to give strength to the coarse thread or slubbing which is thus produced.

The slubbing is lapped round the spindle, but the clasp being higher than the upper ends of the spindles, the direction of the slubbing is not quite at right angles to the spindle; hence the spindle, when it is turned round, will give twist to the slubbing, without winding or gathering it

up upon the spindle, because the slubbing always slips over the top-end of the spindle; but when a portion of each slubbing is finished, and it is required to wind it up round the spindle in a ball, the slubbing must be pressed down by a wire 8, so as to bear it from the point of the spindle, and place it opposite to the middle part of the cop or ball upon the spindle, and then the motion of the spindle will cause it to wind up upon the spindle, and form a ball.

The wire 8 is made to operate upon the whole row of slubbings at once, and for this purpose a horizontal rail 4 is placed in the front of the row of spindles, being provided with pivots at its extreme ends, on which it is supported in standards rising from the carriage D. It has a small arm or lever projecting from it at each end, and the wire 8 is stretched between these arms. By turning the rail 4 round upon its pivots, the wire is capable of being raised up, as in the figure, or lowered down at pleasure: when the wire is lowered, it descends below the level of the top of the spindles, so as to bear down the threads which, when the wire is raised up, as shewn in the figure, proceed from the points of the spindles.

The spinner holds the rail 4 in his right-hand, and it is by this that he draws the carriage either in or out, according as it may require; and by turning the rail 4 round, he can elevate or depress the wire 8, so as to make it bear down the slubbings to any degree at pleasure; by this means, he distributes the slubbings upon the spindles in a proper manner, to form a regular ball or cop, as shewn in the figure.

As the cardings are very slight and tender, they would be liable to break if they were dragged forwards on the inclined cloth, or even if the cloth were to be moved round its roller by the force applied to the cardings. To avoid this, a cord is applied round a groove in the middle part of the upper roller, and after passing over proper pulleys, as shewn in the drawing, it has a weight suspended to one end, and a smaller weight to the other; the small weight is only to keep the rope tight, but the large weight tends to turn the rollers and endless cloth round in a direction to deliver out the cardings, so that there will be no strain on them. Every time that the carriage is wheeled home, the large weight is wound up by means of a piece of wood projecting from the carriage, which seizes a knot in the cord at the part which lies horizontally; this pushes the cord back a certain distance, so as to draw up the great weight; but the endless cloth cannot turn backwards, because there is a ratchet and click at one end of the roller which prevents it; the rope, therefore, slips round upon the roller. When the carriage retires, the great weight turns the roller and endless cloth round, so as to deliver out the cardings at the same rate as the carriage retreats and takes them up; but when the proper quantity is given out, the knot in the rope arrives at a fixed stop, which does not permit it to move any farther; and at the same instant the roller 5 quits the lever 6, and allows the upper rail G of the clasp to fall, and hold the carding fast from being drawn out any farther; the wheel E is then put in motion to turn the spindles round, and the carriage is drawn back, which extends the slubbings, and twists them at the same time, as before mentioned.

When the carriage is drawn out to its full extent, and the necessary twist is given, the wire 8 is put down to bear down the slubbing from the point of the spindle, and the motion of the wheel being continued, the slubbings are wound up upon the middle part of the cop or ball which is formed upon the spindle; but as fast as the slubbings are wound up, the spinner must push back the carriage towards the clasp; and he must turn the wheel round at such a rate that the

spindles will not wind up any faster than the carriage returns, otherwise the slubbings would be broken or unequally stretched; he must also raise and lower the wire 8 continually, by turning the rail 4 round in his hand, in order to distribute the slubbing on the cop in a regular manner, so as to make a firm ball or cop.

A child attends the machine to bring the cardings from the carding-machine, and place them upon the inclined cloth; and when they are exhausted, fresh ones are joined on, so as to keep the machine constantly supplied.

The degree of twist which is given to the slubbing is regulated by the discretion of the spinner in turning the wheel at a proper rate, corresponding to the quickness with which he draws out the carriage. Slubbings which are intended to be spun into yarn for the warp of the cloth require to be more twisted than the slubbings intended for the weft; but the proper quantity of twist depends on the fineness of the wool, and the length of its fibres. In general it may be stated, that no more twist is given to the slubbings than is necessary to make them draw out to the required extent without breaking. This twist is of no use to the yarn, because the slubbing will be twisted in the contrary direction, when it is spun the second time in the jenny.

An improved slubbing-machine has been introduced, which is put in motion by the mill, and the carriage is made to draw out by the power of the machine. The spinner has only to push the carriage in, and turn the handle, in order to wind up the slubbings; by this means, a greater degree of regularity is attained in the quantity of twist which is given to the slubbings when they are drawn out. The movements to effect this are taken from the mule used in cotton-spinning. See *Manufacture of COTTON*.

Spinning Jenny.—In this machine, the slubbings are spun over again, and reduced to the requisite fineness for weaving. The jenny has nearly the same parts as the billy, but differently arranged. The spindles are placed at one end of the frame, and the clasp which holds the slubbings is placed on the carriage, so that it can be moved backwards and forwards, to and from the spindles by the spinner, in order to draw out and extend the yarn at the same time it is twisted.

A perspective view of the jenny is given in *Plate II. Woollen Manufacture*.

The spindles 3, 3, 3, are placed perpendicularly at about four inches asunder at one end of the frame AA of the machine. The lower extremities of the spindles are pointed, and turn in small cups or sockets in a cross-rail of the frame; they are supported near the middle of their length by passing through brass-collars in a horizontal rail. Near the lower end of each spindle a small pulley is fixed, to receive an endless band, which passes round the horizontal cylinder or roller 2, about six inches diameter. The cylinder is supported on pivots at its ends in the sides of the frame, and lying in a direction parallel to the row of spindles, it turns them all round by a small band for each. This cylinder is usually made of tin-plate, that it may not alter its figure by the weather, as wood would do; and its surface is covered with coarse brown paper, to prevent the bands from slipping upon it. The cylinder 2 is put in motion by a strap or band 1, 1, which passes round a pulley at the end of it, and also round the great wheel BB, which is supported in a framing suspended over the machine from the ceiling, but which is not shewn in the drawing. The wheel B is turned by applying the right-hand to the winch B. In front of the row of spindles, and about a foot higher than their points, a long cross-rail 16 is situated horizontally: it is supported at each extremity by being mortised into blocks of wood cc, which are furnished

with small wheels or castors, forming a sort of carriage, to run horizontally upon the side-beams of the main-frame in grooves, which guide them, so that the rail 16 can be moved backwards and forwards through a space of about six or seven feet, in a horizontal position, without varying from its parallelism with the row of spindles. The underfide of the rail 16 is formed into a number of narrow notches for the slubbings to pass through; and these notches are partly filled up by projecting pieces, rising up from a second cross-rail 5, 5, so as to form the clasp which confines or pinches the slubbings in the notches when the lower rail is raised up; but the slubbings can draw freely through the notches when the lower rail is let down. This lower rail is guided and limited to move up and down only a small space by staples, which project downwards from the rail 16, and receive the ends of the lower rail 5 of the clasp. The rising and falling of the lower rail is effected by small cords fastened to it at about every yard of its length; these cords are conducted over small pulleys (concealed in the substance of the upper rail 16), and are all attached to a handle, situated over the middle of the upper rail at 16, and beneath an arched bar, which is fixed on the top of the clasp. The spinner holds this handle in the left-hand, whilst the right is employed in turning the wheel; and by the fingers of the left-hand she can raise up the lower rail 5 of the clasp, and draw it close to the upper one. It will then be retained in that position by a small spring-catch, and will clasp the slubbings fast in the notches, through which they pass; but when the spring-catch is pushed back, so as to relieve the handle, the lower rail will fall down by its own weight, and release the slubbings, to allow them to slide through the notches.

The cops of slubbings which are to be spun are supported in an inclined frame 4, 4, fastened within the main frame of the machine. The cops are mounted upon iron wires; they are placed in two rows, one above the other, as shewn in the drawing; but each row should only contain half as many cops as there are spindles.

Each slubbing is conducted through a notch in the clasp, and thence it proceeds nearly in an horizontal position to the spindles 3, 3.

When the yarns have been drawn out and twisted they are wound up on the spindles in balls, in a similar manner to the billy. The wire which is used for bearing down the thread from the points of the spindles is marked 12; it is attached to a horizontal rail, which is supported on pivots at its ends, close to the row of spindles. There is a small pulley 11, fixed at one end of the rail, and a short lever at the other, which lever is hidden in the drawing by a part of the framing. Between the pulley 11 and the lever, the wire 12 is extended, and by turning the rail round upon its pivots, the wire will have a motion up or down.

The spinner can communicate motion to the pulley 11 by means of a cord 7, 7, which passes round it, and extends the whole length of the frame, the end being made fast to a pin at A; this cord lies over the surface of one of the blocks 6, which contains the wheels of the carriage, and passes between three small pulleys 9, 6, and 8. The centre pins of the pulleys 9 and 8 are fixed to the block; but the centre pin of the pulley 6 is fixed to a small slider, and can be drawn in the direction of the rail 16, by applying the finger to a small trigger near the handle 16. This action removes the pulley 6 out of the line of the other two pulleys, so as to shorten the cord 7, and turn round the pulley 11; this brings down the wire 12, and bears down the threads upon the spindles. A small counterweight is suspended from the wheel 11, to return the wire to its former position when the pressure of the finger on the trigger is removed. By

this movement, the spinner has full command of the wire 12, to raise or lower it in any degree she thinks proper; and this is done independently of the motion of the carriage, because the pulleys 9, 6, and 8, run freely along the cord 7, and their motion has no tendency to move the wheel 11 either way.

The jenny is worked by one person, who stands within the frame, and turns the wheel B with the right-hand, whilst he holds the clasp in the left, so as to run it backwards and forwards along the frame at pleasure. The slubbings are drawn between the moveable rails 16 and 5, in the notches of the clasp, and each slubbing is fastened on to its corresponding spindle. The clasp being left open is drawn backwards from the spindles, and the slubbings run freely through the notches of the clasp; the slubbings are drawn off the balls at 4, when the clasp retires from the spindles, until a certain length of each slubbing is drawn out and extended nearly in an horizontal position between the spindles and the clasp: this length is regulated by a mark made on the frame of the machine, to indicate when the clasp has arrived at its proper position. The bars of the clasp are then brought together by raising up the handle under the catch, as before described, and it fastens all the slubbings in the notches. This being done, the spindles are put in rapid motion by turning round the large wheel B B; they twist those parts of the slubbings which are extended, and the motion being in a contrary direction to the twist of the slubbing, the first tendency is to untwist the slubbing, at the same time that the carriage and clasp are gently drawn back, or from the spindles. By this means, the slubbings are stretched or drawn out in length at the same time that they get a new twist in the opposite direction; this keeps them from breaking, and when they are drawn to their intended extent by the carriage being moved back to the stops at the extremity of the main frame, the great wheel is turned round as many turns as is necessary to give them all the twist which those portions of thread are intended to have.

The threads extended between the clasp and the spindles are now finished, and it only remains to wind them up upon the spindles, previously to drawing out a fresh portion of each slubbing, in order to spin it in the same manner. To wind up the threads, they are pushed down upon their respective spindles, by pressing the trigger which moves the wire 12; and the motion of the great wheel B is continued, in order to wind up the slubbings in balls upon the spindles, at the same time that the carriage and clasp are pushed back towards the spindles. When the carriage is got home, the thread is finished and wound up, and a fresh portion of slubbing is extended. To do this, the lower rail of the clasp is dropped down, and it releases the slubbings; the carriage is then drawn back to the mark upon the frame, as before described, which shews that a proper length of each slubbing is drawn off from the balls, and extended between the spindles and the clasp. The clasp is then closed, and the wheel B put in motion to twist the threads whilst the carriage is drawn out; thus the spinning operation is repeated as before, and prepares another length of each of the threads. When finished, they are pushed down from the points of the spindles, in order to make them wind up thereon in the balls, as before.

There is some discretion required in spinning with the jenny, to draw out the carriage with a movement correspondent to the rapidity with which the spindles give the twist, or rather untwist, to the slubbing; for the principal extension of the thread is effected whilst the slubbing is untwisting, and whilst the first portion of twist is given to the threads. These motions must be properly proportioned by the

WOOLLEN MANUFACTURE.

the spinner, who must also be careful to give an equal degree of twist to each successive portion of thread which is spun, otherwise the thread will consist of hard and soft places.

When the yarn is intended for the warp of the cloth, the spindles are turned for a given time after the thread is extended to its full length, as we have before mentioned; but for the yarn which is to be used as weft, it is different: the whole of the twist is given during the extension of the thread, and none afterwards; this difference is to render the weft softer than the warp, because in the cloth the weft appears more on the surfaces than the warp, and it is principally the felting and interlacing of the fibres of the weft that will form the surface of the cloth when finished.

The yarns are usually extended in the jenny two and a half or three times the length of the slubbings from which they are spun; and that degree of twist given to them which is suitable to the purpose for which the yarn is to be employed.

The *Mule for spinning of Yarn* is very nearly the same machine as the mule for spinning cotton; this is used for spinning some kinds of woollen yarn instead of the jenny. When the mule is employed for spinning yarn for weft, it is used in the same manner as described in our article *COTTON Manufacture*; but for spinning warp, the spindles are made to revolve, and twist the thread some time after the carriage is run completely out, and the stretching of the yarn is finished. There is a movement in the machine that shifts the endless strap which turns the mule upon a larger pulley, as soon as the carriage is run fully out, so as to give a more rapid motion to the spindles after the stretching, or drawing out, is finished, than they had during the drawing back of the carriage. By this means some time is saved, because the spindles may be allowed to run very quick when it is only required to twist the threads; but whilst the extension is going on, the twisting motion must be moderate, or the threads would be broken. A very similar movement is used in the mule for spinning cotton, and is called the double-speed; but the description of this mechanism is omitted in the article *MANUFACTURE*.

The mule has not, till lately, been in much repute for spinning woollen yarn, and the jenny is still thought to spin better yarn: but we have no doubt that when certain modifications are made, it will become a much more perfect method than the jenny, being much less dependent on the discretion and dexterity of the spinner; for if the machine is once constructed so as to spin properly, it will always continue to do so.

To keep the yarn to the size which is intended, a few of the coppins are reeled off, in order to measure out a certain length of the yarn, which is weighed; and if it does not prove of the weight expected, the quantity of wool which is spread over a given surface of the feeding-cloth of the carding-machine must be increased or diminished accordingly; and when the right quantity is formed, the lead weights which are used for weighing the given quantity of wool are altered to suit it. The draft of the jenny may also be altered to effect the same thing.

The spinning processes are now finished, and it remains to weave the yarns into cloth. From the description we have given, it will appear that woollen yarn is spun in a very different manner from cotton. The opening processes and the scribbling and carding are very similar, except that the carded wool, instead of being drawn into a continued sliver like cotton, with the fibres stretched the lengthways of the sliver, is formed into separate rolls, with the fibres disposed crosswise or spirally round the roll.

By the slubbing-machine these are joined together, drawn

out in length, and slightly twisted, by operations similar to that of roving in cotton-spinning; but the operation of drawing, which is so frequently repeated for cotton, would be useless, and to a certain extent even prejudicial for wool. The object of that process is to elongate and stretch the fibres of the cotton straight, and lay them parallel to each other; but it does not reduce the sliver to a smaller size, because as many times as the sliver is extended in length, so many slivers are put together into the drawing-frame at once, leaving the sliver which has been drawn the same size as it was before, but elongated to three or four times the length, and all its fibres fully extended.

As woollen cloth is intended for felting, it is not desirable to straighten the fibres, but only to disentangle all knots, and unfold any fibres which may be doubled, also to lay the fibres in the direction of the length of the thread. There is a natural curl in the fibres of wool which should be preserved, and will contribute to the firmness with which the fibres will entangle in the felting.

The operation of spinning by the jenny and billy are very similar, but both differ from the manner in which the extension is made in the cotton spinning-machines by rollers. In the jenny, the extension is made upon a considerable length of the carding or slubbing at once; but in the rollers, the length of cotton which is submitted to the action of drawing out is very short, indeed very little longer than the length of the fibres of the cotton. In mule spinning both modes of extension are practised; first, drawing the roving by rollers, and then a certain length is stretched out to a greater extent.

Warping.—The coppins of yarn are mounted on wires in a frame, and the yarns are drawn off from them, in order to combine a sufficient number of them together, to form the warp for the web of cloth which it is intended to weave. For instance, for making the cloth called double drab, which we shall take as an example, 2960 threads, each 65 yards long, are laid parallel to each other; but a separation is preserved at every 40 threads, dividing the whole into 74 parcels, for the convenience of the weaver.

The warping is performed by the warping-mill, which is a large reel, with its axis horizontal; the ends of the threads are made fast to the reel, which is turned round, and it draws the threads off the coppins, so as to wind them upon its circumference; and to prevent the different turns of the threads from lying one over another, the threads are guided through an eye or ring affixed to a slider, which is moved along a wooden rail, in a direction parallel to the axis of the reel, by a cord that winds round one end of the axis of the reel.

A warping-mill for silks is described in our article *SILK*, and will give a clear idea of the present, which only differs in the horizontal position of the axis, and in the greatness of its dimensions. The threads for the warp being thus assembled together, are taken off the reel, and rolled up into a bundle.

The warp is then scoured in urine, to remove the greasiness of the wool, and is next sized; to do this, it is dipped into the cauldron of size, about ten yards in length at a time, and well worked in by the hands. After sizing, the yarns are stretched out at length in a field, till they are dry, and the warp is then ready for the loom.

The yarn for the weft is wound off from the cops of the jenny to the quills or small bobbins, which are to be put into the shuttle.

The loom for weaving broad-cloth has the same parts as the simple loom described in our article *WEAVING*; but it is made very strong, to enable it to resist the strain of weaving

such broad and heavy cloth. The fly-shuttle, invented by John Kay in 1737, is now in general use; it enables one weaver to do the work, which formerly employed two men at opposite sides of the piece, to throw the shuttle from one to the other, the width being greater than a man can reach. The warp is wound on the yarn-beam, which is placed in the loom, and the threads being drawn through the beddles and the reed, and fastened to the cloth-beam, the loom is ready for working, in the usual manner of weaving plain cloth. At each edge of the warp a few threads of strong and coarse yarn are placed; these form what are called the lifts when the cloth is woven, and serve to give strength to the cloth, and receive the hooks by which the piece is stretched in the tenters after milling.

The width of the cloth is measured between the lifts and the number of yarns, which we have specified will make 100 inches in width for the double drab-cloth, or for common cloth 3000 threads will make a piece 103½ inches wide. The quantity of weft used for these cloths is upon an average one pound weight to a yard in length. The length of the warp contracts a little in the weaving, so that the sixty-five yards of yarns will make only sixty-two yards of cloth.

Scouring.—The piece of cloth must be cleansed from the greasiness of the oil before it can be felted; for this purpose, it is first soaked three hours in a mixture of urine and pig's dung, it is then scoured in the mill for two hours, and lastly, for half an hour with fair water. The scouring is performed at the fulling-mill by a pair of stocks. (See *FULLING-Mill*.) The pair of stocks are two large wooden hammers, suspended with the helves or handles in an inclined position, and the heads are lifted in succession by cogs or tappets, fixed on the axis of a water-wheel. When the cogs quit the hammers, they fall by their own weight, and strike the piece of cloth, which is contained in a wooden cistern or trough, in which the hammers work. The action of the hammers is to beat and compress the folds of cloth, and to turn the piece continually round in the trough or cistern in which it is placed. The form of the trough is such, that the weight of the piece of cloth causes it to occupy the lower part of the trough, and each hammer when it descends drives the cloth out from this lowest part, and forces it up a curved sweep. When the hammer is lifted up, the cloth falls again into the space which it before occupied, and at the subsequent descent of the hammer it is again driven out; the heap of cloth is of a considerable bulk, and this action of the hammers is chiefly on the lower part of the heap; the beaks of the hammers strike nearly horizontally under it, as it were to undermine the heap, so that the top part falls over when the hammers retreat. This action causes a continual circulation or turning round of the piece of cloth within the trough, and effects the scouring, by continually bending and folding the cloth in a fresh direction; and as the strokes act upon a great number of folds at once, the different surfaces of the cloth are caused to rub against each other, with a very similar action to washing cloth by hand.

When the scouring is finished, the piece of cloth is taken out, and extended in a vertical plane, in a frame called the tenter, where it remains till dry.

The *tenter* consists of a number of vertical posts fixed in the ground with a continued horizontal rail, which is fixed on the top of them, and is as long as the piece of cloth; there is also another line of horizontal rails, which are fitted between the upright posts, so as to slide freely up and down; and they can be fixed at any distance beneath the upper rails by means of pins in the posts, according to the width of the piece of cloth. Both the upper and lower horizon-

tal rails are driven full of tenter-hooks, which are small iron rails sharpened at both ends, and bent at right angles, like an L; on these hooks the lifts of the cloth are fastened, and the lower or moveable rails are fixed at the proper distance beneath the upper rails, in order to extend the cloth to its full width.

Burling.—The cloth being dried is burlled, that is, examined minutely in every part, and all knots and uneven threads or straws, or extraneous matters, removed; any rents or defects which can be found are repaired, by introducing fresh threads. This being done before the milling or felting, the fibres of the new threads will become so entangled as to render such defects nearly imperceptible in the finished cloth.

Fulling-Mill for felting the Cloth.—There is another kind of stocks in a fulling-mill; but the shape of the trough in which the stocks or hammers work on the cloth is different from that described in the article *FULLING-Mill*, which is only proper for scouring. In order to subject the cloth to the blows of the hammers, the trough for milling is formed in such a manner that the cloth cannot escape from them, because that part of the trough which is opposed to the beaks of the hammers is nearly a flat surface, and perpendicular to the direction in which the hammers strike, so that the cloth is actually beaten between the beaks of the hammers and the flat bottom or rather side of the trough.

The hammers are made to strike very heavy blows; but they do not bruise or injure the cloth, because there is always a great number of folds of cloth on which they strike. The helves or handles of the hammers are placed in a different position from the scouring-stocks, in order to make the hammer-heads fall in a more perpendicular direction when they make their stroke, and hence they strike with more force. On this account they are called falling-stocks, whilst those used for scouring are called hanging-stocks, in which the helves of the hammers being nearer to the perpendicular, the heads move in a more horizontal direction, in the manner of a pendulum, and exert less force on the cloth; the other difference is, that the hammers of the scouring-stocks only drive the heap of cloth round in the trough, there being no part directly opposed to the beaks of the hammers but a fair curve, which is so much inclined to the direction in which the hammers move, that the cloth mounts up the inclined curve when the hammer strikes, and evades the direct force of the blow.

There is another kind of fulling-stocks, in which the trough and hammer are constructed with a view to mill or felt the cloth; but the hammers are put in motion in a different manner: thus the helves are suspended in a vertical position, like pendulums, and the force of the cogs on the horizontal shaft, which is turned by the water-wheel, is applied to drive the hammers forwards against the cloth, and produce the felting. To return or draw back the hammers, a chain is attached to each, and these chains are linked to the opposite ends of an horizontal lever, like a scale-beam, which is fixed in front of the stocks. This lever and chains draw back one hammer when the other is pushed forwards; and as the hammers are actuated alternately by the cogs, a constant action is kept up.

The most simple fulling-mill by a water-wheel has no other wheels, but the tappets or cogs which lift the hammers are fixed immediately into the axis of the water-wheel, and it usually gives motion to two pair, one at each side of the wheel. It rarely happens that this construction of a mill allows the water to be used to the greatest advantage, because the circumference of a water-wheel should not move with a greater velocity than between 180 and 240 feet *per* minute;

minute; and the hammers of a fulling-mill should be so timed, that each one will make from about 30 to 36 blows *per* minute. This requires that the cogs for the hammers should be numerous, and fixed in the circumference of a large wheel fixed on the axis of the water-wheel, otherwise the water-wheel must be made to turn so quickly as to lose a great part of its force. A better way is to apply a cog-wheel on the axis of the water-wheel to turn a pinion on the horizontal shaft, which carries the cogs for the hammers, and this horizontal shaft may have a fly-wheel upon it, to regulate the motion and render it uniform.

Mr. Smeaton's proportions for a fulling-mill for two pair of stocks were as follows:—The water-wheel, 14 feet diameter, 7 feet broad; it was a breast-wheel, and the fall of the water was five feet from the surface of the mill-pond to the tail-water below. The spur-wheel on the axis of the water-wheel 72 cogs, and $9\frac{1}{2}$ feet diameter; the lantern turned by it 23 rounds. Upon the same shaft as this lantern was a fly-wheel of eight feet diameter, with a rim of cast-iron seven inches square, and also the two cogs or tappets for each of the four hammers forming two pair of stocks. The same mill was adapted to be turned by the power of horses in dry seasons; for this purpose, another lantern of 13 teeth was applied on the other end of the same horizontal axis, which could be occasionally turned by a horizontal cog-wheel of 90 teeth and 12 feet diameter, fixed on the vertical shaft, which the horses turned. The levers by which the horses drew were 15 feet long, so that the horses' track was 30 feet diameter.

It required four horses to work one pair of stocks in this mill, and when Mr. Smeaton tried the expenditure of water at this mill, and also at another mill with an overshot-wheel, he found it required from 1200 to 1400 cubic feet of water *per* minute, falling one foot, to work a pair of stocks. Taking the force of a horse at 352 cubic feet *per* minute raised one foot, this is very nearly equal to four horses. These stocks were used for fulling of bays, and we apprehend the power for working the fulling-mills for broad-cloth is greater.

Process of Milling.—A piece of cloth of sixty-two yards long has six pounds of soap allowed for it, which is dissolved in water, and a handful spread upon every yard in length; the piece is then put into the trough of the mill, and worked for three hours; during this time the cloth is frequently moved in the trough, to expose fresh surfaces to the action of the hammers. The blows upon the cloth cause a motion of the fibres of the wool amongst one another, and the soap facilitates this motion; the fibres of the wool have the singular property of moving always forwards in the direction of the roots of the hairs, when a number of hairs are rubbed or worked together, but they will not retreat in the opposite direction; this produces the matting or entangling of all the fibres together. After three hours milling, the piece of cloth is taken out of the trough, and soaped again, then returned and milled again for three hours. This is repeated four times, making twelve hours milling in the whole, and then a stream of fair water is admitted into the trough, to wash away the soap. The piece of cloth, when taken out of the mill the last time, is generally found reduced to about 60 inches broad, and 40 yards in length; before the operation, it was 100 inches broad, and 62 yards in length.

The operation of felting is so well explained by M. Monge, in the *Annales de Chimie*, that we think proper to give an extract from his memoir, in addition to what is stated in our articles FELTING, FULLING, and WOOL.

If we examine a human hair, a fibre of wool, or the hair of a rabbit, hare, beaver, &c. in a microscope of the greatest

magnifying power, the surface of each hair appears smooth and even; or at least if any inequalities are perceptible, they seem rather to arise from some difference in the colour and transparency of particular parts of the fibres than from the irregularity of their surfaces; for their images, when viewed by a solar microscope, are terminated by even lines, without any roughness. Nevertheless it is probable the surfaces of these objects are formed either of *laminae*, which cover each other from the root to the point, much in the same manner as the scales of a fish cover the animal from the head to the tail; or still more probably of zones placed one over the other, like what is observed in the structure of horns; to this conformation it is, that such substances owe their disposition to what is called felting.

If with one hand we take hold of a hair by the roots, and draw it between two fingers of the other from the root towards the point, we are hardly sensible of any friction or resistance, nor can we distinguish any sound; but if, on the contrary, we draw it between the fingers from the point towards the root, we are sensible of a resistance which did not exist in the former case. A sort of tremulous motion is also produced, which is not only perceptible to the touch, but may also be distinguished by the ear.

It is evident, therefore, that the texture of the surface of a hair is not the same from the root towards the point, as from the point towards the root. As this texture is the principal object of the present memoir, it is necessary to demonstrate it by some other observations.

If a hair is held between the fore-finger and thumb, and rubbed by them backwards and forwards alternately in the direction of its length, a progressive motion of the hair will take place; but this motion is always with the root forwards, although the rubbing of the finger and thumb is alternately in both directions. This effect does not at all depend on the nature of the skin of the fingers, or its texture; for if the hair be turned, so that the point is placed where the root was, the movement then becomes contrary, *viz.* its motion is always directed towards the root.

What is observed in the above instance is entirely analogous to what happens when country children, by way of sport, introduce an ear of rye between the wrist and the shirt-sleeve; the points of the beards of the ear are directed outwards, and by the various motions of the arm, this ear, sometimes catching against the shirt, sometimes against the skin, takes a progressive motion backwards, but the beards always resist its return, so that it soon gets up to the arm-pit. It is very clear, that this effect is produced by the asperities upon these beards, which being all directed towards the point, do not permit the ear to move in any other direction than towards that part which was united to the stalk. There can be no doubt that it is the same with respect to hair, and that its surface is beset with asperities, which being laid one upon the other and turned towards the point resist all motion, except towards the root.

These observations, which it would be useless to multiply, relate to long hair, which have been taken as examples; but they apply with equal propriety to wool, furs, and in general to every kind of animal hair. The surface of all these is, therefore, to be considered as composed of hard *lamelle* placed one upon another, like tiles, from the root to the point; which *lamelle* allow the progressive motion of the hair towards the root, but prevent a similar motion towards the point.

From what has been said, it will be easy to explain why the contact of woollen stuffs is rough to the skin, while that of cotton or linen cloths is smooth: the reason is, that notwithstanding the flexibility of each particular fibre, the asperities

perities upon the surface of the fibres of the wool, by fixing themselves in the skin, produce a disagreeable sensation, at least till we are accustomed to it; whereas the surface of the fibres of hemp or flax, of which linen is made, being perfectly smooth, do not cause any such sensation. It is also probable, that the injury arising to wounds or sores from the application of wool does not proceed so much from any chemical properties, but is occasioned solely by the form of the surface of the fibres, the asperities of which attach themselves to the raw and exposed flesh, which they stimulate and irritate to such a degree as to produce inflammation.

The asperities with which the surface of wool is every where surrounded, and the disposition which it has to assume a progressive motion towards the root, renders the spinning of wool and making it into cloth difficult operations. In order to spin wool and afterwards to weave it, we are obliged to cover its fibres with a coating of oil, which, filling up the cavities, renders the asperities less sensible; in the same way as oil, when rubbed upon the surface of a very fine file, renders it still less rough.

When a piece of cloth is finished it must be cleansed from this oil, which, besides giving it a disagreeable smell, would cause it to soil whatever it came in contact with, and would prevent its taking the colour which is intended to be given to it by the dyer. To deprive it of the oil it is scoured at the fulling-mill, by working it with hammers in a trough full of water or urine, in which fuller's-earth is sometimes mixed. This earth combines with the oil which it separates from the cloth, and both together are washed away by the fresh water, which is afterwards brought to it in the machine. Thus after a certain time the oil is entirely washed out of the cloth.

The fulling, which succeeds the scouring of the cloth, is aided by the application of the soap. The alternate pressure given by the hammers to the piece of cloth, especially when the milling is pretty far advanced, occasions an effect analogous to that which is produced upon hats by the hands of the hatter; the fibres of wool which compose one of the threads, whether of the warp or the weft, assume a progressive movement with their roots forwards, and introduce themselves among the fibres of the threads nearest to them, then into those which follow; and thus by degrees all the threads, both of the warp and the woof, become felted together. The cloth, having by the above means become shortened in all its dimensions, and thickened in its substance, partakes both of the nature of cloth and of that of felt; for at the same time that the threads give it considerable strength, it may be cut without being subject to ravel, and on that account we are not obliged to hem the edges of the pieces of which wearing apparel is made. Lastly, as the threads of the warp and those of the weft are no longer so distinct and separated from each other as to leave interstices between them, the cloth forms a warmer clothing, independently of its having acquired a greater degree of thickness. Knit worsted is also rendered less apt to run, in case a stitch should drop, by the operation of fulling.

Tentering.—When the milling is finished, the cloth is stretched again on the tenter. It is usual to extend the piece to forty-two yards in length, but not at all in breadth; indeed only one inch of extension in each yard is allowed by law. The cloth remains in the open air until it is perfectly dry and ready for the succeeding operations of finishing, which are only intended to give it a beautiful surface, for it already possesses all the useful qualities of cloth.

Dressing the Cloth with Teafels.—This operation is to raise up the nap or loose fibres on the surface of the cloth, by

scratching it over with a species of thistles called teafels, in order to form a wool on the surface, which can be removed by shearing. The teafels are the balls or ears which contain the seed of the plant called *dipsacus fullonum*; the scales which form the ball project on all sides, and are terminated with sharp points, which turn downwards, like hooks, and are very elastic. See TEASEL.

A number of teafels are put into a small frame, which is composed of a handle eight or ten inches long, having a small stick passed through it at one end about eight inches long, which is split into two at each end nearly all its length. There is also another similar stick, which is passed through the handle near the middle of its length; the two split sticks are perpendicular to the stem or handle, and parallel to each other. The space between them is filled with teafels, which are jammed in very fast between them, and also in the clefts of the split sticks, where they are secured by strings extended between the ends of the split sticks, and twisted, until they draw the sticks forcibly together, and bind the teafels very fast. This frame filled with teafels forms a tool, which very much resembles the curry-comb used to clean horses, and is used in a similar manner, to scratch over the whole surface of the cloth, and draw out all loose ends of the fibres of the wool, which are not firmly confined by the entanglement of the felting.

The dressing is performed by two men, who hold the teasel-frame by its handle, and work the cloth, when it is hung up in a vertical position over two rails fixed to the ceiling; when they have worked over as much surface as they can reach, they draw down a fresh portion, which they work in turn, and thus proceed until they have finished the whole piece. The first time the cloth is dressed it is wetted with water; it is worked three times over in the wet state, by strokes in the direction of the length of the piece, and then it is worked again three times in the other direction; by this means all the fibres are raised, and the cloth is prepared for shearing.

In the most improved manufactories, the dressing is performed by the gig or gig-mill. This is a cylinder covered on its surface with teafels, and turned rapidly round whilst the cloth is drawn over it.

The *Gig-mill* is represented in perspective in *Plate V. Woollen Manufacture*. M is the wood frame of the machine; FF is the cylinder or drum, which is composed of 12 rails or troughs, filled with teafels FF, 3, 4, &c. These are fastened on the circumference of two or three wheels fixed upon a wooden axis 7; the drum is put in motion by a pulley ED at one end of its axis, which receives an endless strap, 2, from the drum C, situated above the machine. There are two pulleys, E and D, one fixed fast on the axis, and the other fitted on loosely, with liberty to turn round freely upon it; the strap can be shifted to either pulley, and accordingly the machine will be put in motion, or will stand still.

The drum C is fixed on one end of an iron shaft 1, which is put in motion by a bevelled wheel B, from the larger wheel A, fixed on the great horizontal shaft, which proceeds the whole length of the mill. The drum, FF, covered with teafels, is mounted on bearings supported by the frame, and the piece of cloth G is conducted over it, to receive the action of the teafels; one end of the piece of cloth is wound round a roller J, and the other end of the piece is wound on the roller L; both these rollers are put in motion from a bevelled wheel 6, fixed on the extremity of the axis of the drum; this turns a wheel H upon an inclined axis, which has a pinion at each end; one of these pinions, 9, turns a bevelled wheel, K, on the end of the axle of the upper roller

WOOLLEN MANUFACTURE.

roller L; and the other, 8, turns the wheel I belonging to the lower roller J. By means of this wheel-work both rollers are turned round in the proper direction, to make the upper roller L wind up or draw the cloth, whilst the lower roller unwinds and gives out the cloth. N is a pipe, which conveys water to the machine; it is pierced with a number of holes to throw jets of water on the cloth, and wet it.

As fast as the cloth is taken up by the roller L, it is given out by the other roller J, and is then drawn over the surface of the cylinder, as at G, the teasels of which, as it revolves, act very effectually on the cloth to raise the nap. When the whole piece has passed, and is gathered up on the roller L, the machine is stopped, by shifting the strap z to the loose pulley D, then the two rollers L and J are exchanged, and the operation is repeated as before, and so on till the nap is sufficiently raised.

The mode of repeating the action on the cloth by exchanging the rollers is troublesome, and a better mode is to provide the means of disengaging either of the wheels K or I from its respective pinion, making the machine so that only one wheel and pinion can be engaged at once; also to make the motions in such direction that the roller which is engaged shall always wind up the cloth upon itself. Each roller must have a small wheel upon one end of it, as shewn at 10, with a lever and weight 11, to press upon the circumference of the wheel with such force as to occasion a friction, and make the cloth draw tight when it is drawn off the roller. In this way, the cloth can be made to work either backwards or forwards; because that roller which is engaged with the wheel-work will wind up the cloth, and draw it off from the other roller across the drum; but when all the cloth is wound off, that roller which has taken the cloth must be disengaged, and the other put in action, which will make the cloth work back again.

The most improved gig-mills used in Yorkshire have a still better method of moving the cloth. This is by means of a pair of rollers in the place of the upper roller L: they are turned round by a large spur-wheel on the end of the roller, which works in a smaller wheel on the end of the drum; one roller is mounted over the other, like the two rollers of a flattening-mill, and pressed together by screws with sufficient force to draw the cloth between them. The piece of cloth, when brought to the machine, is laid down on a board on the ground before the machine, and one end is passed under the roller J, which is merely to guide it; then it is carried over the drum, as at G, and introduced between the pair of rollers at L, which draw it slowly forwards; from these the cloth turns upwards, and is extended horizontally over two rollers which are suspended from the ceiling. After quitting these rollers, it descends perpendicularly, and is gathered on the ground in folds on a board or bench, close to the place where the piece of cloth was laid before the dressing was begun. In order to make the piece of cloth pass a second time through the machine, or as many times as is required, the two ends of it are sewed together, so that it circulates continually over the drum without any interruption or trouble: it is usually done three or four times.

It is an advantage of this method, that the cloth, in descending from the ceiling, hangs perpendicularly, and with that side which has been dressed opposite to the light, so that the workman who gathers it in folds can examine the progress of the work; and when he judges that the cloth is sufficiently dressed, he cuts the sewing which unites the two ends together, and then the end of the piece comes out of the machine, and the cloth is carried away to give place to another piece.

The drum or cylinder of the gig-mill is composed of a number of shallow troughs, fixed on the circumference of the wheels of the drum, and parallel to its axis: into these troughs, frames filled with teasels, like those we have before described, are fastened in a very simple manner; and the frames are placed so close together, that the trough is wholly filled, and forms a continuous surface of teasels to act upon the cloth when the cylinder revolves. When the hooks of the teasels become filled with stocks or fibres of wool, which they have drawn out from the cloth, they are removed from the cylinder, in order to be cleaned by children, who pick out the stocks with a small steel comb.

The teasels are cultivated very largely in the clothing countries; but it sometimes happens, in particular seasons, that the crops fail, and they are then very dear. This has produced many trials of metallic teeth as substitutes for teasels. Mr. Price of Stroud, in Gloucestershire, has two patents, dated 1807 and 1817, for this object; Mr. Laffalle of Bristol took a patent in 1816, Mr. Williams of Fursley in 1817, and Messrs. Lewis of Brinscomb in 1817. We are not informed if any of these inventions are yet brought into real use in the manufacturing district.

Shearing or Cropping the Cloth.—By the operation of the teasels, the wool is become raised all over the surface of the cloth in a loose fur, which must be removed by shearing before the cloth will be fit for wearing, because the fur would gather dirt and dust, and would wear very unequally.

The shears used for cropping by hand are the same as those used in the common shearing-machine, and are represented at E, E, in *Plate III. Woollen Manufacture*. The clothier's shears consist of two very large flat blades of steel, united together by a stem of steel, which is bent into a circular bow, and is sufficiently flexible to allow one of the blades to be moved upon the other, in order to make them cut. Both blades are ground to sharp and straight edges, which apply one to the other, but the blades are not in parallel planes like scissars, for one of the blades is laid quite flat upon the cloth, and the plane of the other blade will then be inclined to the cloth at about an angle of 45 degrees, as is shewn in *Plate III*. The cutting-edge of this inclined blade bears upon the surface of the flat blade, and the spring of the bow is so set, as to press the two edges always in contact. The lines of the edges of the two blades are not parallel to each other, but inclined, so that the edge of the upper blade crosses the edge of the lower blade, and bears upon the flat surface of that blade, at the end nearest to the bow, whilst the other end of the edge of the upper blade is removed over the edge of the lower blade, thus leaving an interval between the two edges, when the shears are open, as is plainly shewn in the figure. In this state, the shears being open, if the lower blade is laid flat upon the surface of the cloth, the nap or wool, which is to be removed by the cropping, will stand up above the edge of the lower blade, in the interval between the two edges; then if the blades be forced together, the edge of the upper blade will pass or cross over that of the lower, and cut away all the wool which projects above the edge of the lower blade. The contact of the cutting-edges begins at the end nearest to the bow, and proceeds regularly to the other, because, as before mentioned, the edges are not parallel to each other. The blades open or return to their former position by the elasticity of the bow, but in order to make the cut they are closed by means of a handle or lever 10, which is fitted or lodged on a round part of the stem of the bow, so as to play thereupon as upon a centre of motion. A double cord is made fast to the lever or handle near to this centre, and the

the other end of the cord is fastened to a block of wood, which is screwed to the flat of the lower blade, and rises up to a proper height. By depressing this handle, the shears are closed, and make their cut with the greatest facility, the elasticity of the bow returning the handle.

The manner of cropping with these shears is as follows:— The piece of cloth is laid down in folds upon a plank or low bench placed on the ground, and the end is drawn across a table or bench, which is covered with cloth, and stuffed with horse-hair, like a cushion. The cloth is stretched out flat upon the surface of the table, and is retained by hooks and weights. Two workmen are employed to shear a piece of cloth; they place the lower blades of their shears flat on the surface of the cloth, with the line of the edge in the direction of the length of the piece; one of the shears is laid on the edge or lift of the cloth, and the other exactly in the middle of the breadth of the cloth. The bows and stems of the shears project over the edge of the table, and the workmen place themselves at that edge. Each man guides the shears with his left-hand, and makes the cut with his right. To hold the shears by, a short staff is lashed to the bow of the shears, and secured by a stay to the lower blade; its direction is nearly parallel to the back edge of the upper blade. The workman puts his arm through the bow as far as the elbow-joint, then lays the fore-arm flat against the staff, which he grasps with the hand; and in this way he has a great command of the shears, leaving the right-hand at liberty to work the handle which closes the shears. This handle is moved backwards and forwards with great rapidity, to make cuts or clips on the cloth, and between every cut the lower blade is moved a small space on the cloth, to cut in a fresh part.

The art of shearing consists in moving the shears with great regularity and parallelism, so that every part of the surface shall be equally cropped. The closeness with which the shears cut is regulated by weights laid upon the flat of the lower blade; these press the blade down into the soft cushion on which the cloth is spread, so that the fur will stand up more above the edge of the blade.

As the two shearers advance in their work, their shears proceed across the breadth of the piece of cloth, and when the man who began in the middle has worked to the lift of the cloth, the other who began at the lift will have worked to the middle, where the first began; the whole breadth is now shorn, and they remove the shears, and draw the piece of cloth forwards across the table, to obtain a fresh surface to work upon.

For shearing common cloth, it is cut wet the first time, then it is dressed again with teasels, dried on the tenter, and cut again in a dry state three times over.

Shearing-Frame.— The most common machine used in Yorkshire is only applied to give motion to the same kind of shears as are used for cropping by hand, and is usually called the shearing-frame. At the side of the table or cushion on which the cloth is spread, a long stool is placed, having grooves at the edges to guide the wheels of a carriage, to which the shears are affixed by their bows. There is a carriage for each pair of shears, and they are slowly and gradually moved along the stool, by a cord which winds upon a roller turned by wheel-work; and at the same time, the handles of the shears are continually pulled by a cord connected with a small crank, which turns round very rapidly. The direction of the cuts is the lengthways of the piece of cloth, and the two pair of shears advance across the breadth of the piece until a whole breadth is cut; the machine is then stopped, the shears removed, and the piece of cloth shifted upon the table. These shearing-frames

operate very well, but require great care and attention to make the different cuttings join, in order to cut equally over the whole surface.

The machine invented by Mr. Harmar of Sheffield was of this description; his first patent was in 1787, and another in 1794. At one period his machines were in general use, but the present shearing-frames, although of the same kind, are very much simplified, and work equally well.

A perpetual Shearing-Machine is represented in *Plate III. Woollen Manufacture*; it is used in the west of England, and is best adapted for narrow cloths. The shears lay crosswise over the piece, which is drawn regularly beneath the shears in the direction of its length without any interruptions; hence it is called a perpetual shearing-machine.

The shears, E E, are the same as what we have already described. Each pair is fastened across the frame by means of a piece of wood, to which the lower blade of the shears are screwed; immediately beneath this blade is the cushion to bear the cloth, which passes between the blade and the cushion. The piece of cloth is wound round the roller C, upon the end of which is a wheel N, and a lever M, which bears up against the lower part of this wheel with so much friction as to make the cloth strain tight in drawing off from the roller. The cloth first passes over a rail B, from which it proceeds in an horizontal direction beneath the two pair of shears E E, then turns over another rail at the other end of the frame, and descends to a roller D, which is turned slowly round by the machinery, in order to wind up the cloth.

The machine is put in motion by the endless strap round the drum F upon a shaft, which proceeds all the length of the mill. The strap turns the pulley G upon the end of the small horizontal spindle H: in this spindle two cranks are formed at *a* and *b*, which are connected, by wires 7 and 8, with the handles 9 and 10 of the shears E, so as to give them a continual motion, and make a cut of each pair of shears every time the spindle H makes a turn. The motion of the machine can be stopped by releasing the lever P, on which the bearing of the spindle is screwed: when the lever P is depressed, and kept down by the catch, as represented in the drawing, the endless strap is drawn tight, so as to turn the spindle; but if the catch is removed, and the lever raised up, the strap becomes loose, and slips round upon the pulley without turning it. A small pulley is fixed upon the spindle at I, to receive an endless strap which passes round a larger wheel J. Upon the same axis with this are three other pulleys of different diameters, which receive a strap 2, and give motion to three similar pulleys fixed upon a spindle 3: the latter spindle has a pinion on the end of it, which works a bevelled wheel fixed on the end of the roller D, and thus it is turned slowly round. The three pulleys on the spindles 3 and J are placed reversed to each other, that is, the smallest pulley on one is opposite to the largest on the other; by this means, the same strap 2 may be shifted, and will work on any of the three pair of pulleys, but each one will communicate a different degree of movement to the roller D, and consequently to the cloth, so as to draw it quicker or slower, and make the successive cuts of the shears at a greater or less distance asunder at pleasure.

The cushions which bear up the cloth against the shears are moveable on centres of motion, and are capable of being raised or lowered. When they are lowered down, the cloth can be readily introduced beneath the lower blades of the shears; and when raised up, they press the cloth up to the shears, and the force of this pressure can be regulated by turning a small handle. In many machines this motion is applied

WOOLLEN MANUFACTURE.

applied to the shears themselves, instead of to the cushion or bed, and is much more convenient.

The perpetual machines answer very well for shearing narrow cloth, when the shears can cut at once across the whole breadth; and then as the two shears work in succession over the same surface, they crop the cloth twice over in passing once through the machine. It has been attempted to shear wide cloths in this machine, by making one pair of shears take one half the breadth, and the other pair the other half; but it is very difficult to draw a wide piece of cloth so evenly over the cushions, as to keep it stretched to the full breadth without any wrinkles in the lengthways of the piece; and if there are any such wrinkles, the cloth will be cut very irregularly. In this particular, the first machines have the advantage, because the cloth is stretched over the cushion by the workman with discretion, and he makes it tight before the cropping is begun.

There have been many patents for the improvements of shearing-machines. Mr. Buffington's, in 1804, is for a method of stretching or extending the cloth breadthways whilst it is in the shearing-frame. His plan is to attach a narrow web of strong cloth to the lifts of the cloth, by sewing or lacing; the outer edge of this web is also sewed to a cord or small rope, so that the cloth becomes edged or bordered with ropes. These ropes are conducted through holes or openings in the frame, which will suffer the cloth and ropes to be moved in the direction of their length; but as the ropes cannot draw sideways out of these openings, the cloth may be continually stretched in its breadth. The openings should have rollers to facilitate the motion of the ropes.

Mr. Joseph Fryer's patent shearing-machine, dated 1802, acts with three shearing-blades, one long one, which extends across the breadth of the piece to form the lower or fixed blade, and two other moveable blades of half the length, which are jointed to the long blade at the two ends, and are moveable thereon, so as to cut in the manner of scissar-blades. The moveable blades are pressed into contact with the edge of the fixed blade by springs, and are put in motion by means of two cranks upon an horizontal spindle, so that the blades make their strokes or cuts alternately. The edge of the lower blade is a straight line, but the edges of the moveable blades are convex on the cutting side, so as to cause them to intersect the edge of the lower blade always at the same angle when they are wide open, as when they are nearly closed.

The piece of cloth is conducted over proper rollers, and wound up by one, which is turned round by the machine, so as to draw the piece of cloth from one end to the other with a slow and progressive motion. The cloth, when it is immediately beneath the edge of the long blade, is bent suddenly over a narrow ridge of metal, which is parallel with the edge of the lower blade, but so far distant as to permit the cloth to pass between them. This ridge of metal is capable of adjustment by means of screws, and can be placed so that the nap of the cloth will be shorn longer or shorter, as it is required.

In some cases, especially in finishing broad-cloths, instead of drawing the piece from end to end, it may be more convenient to cause it, or part of it, to move under the shearing-blades from lift to lift, or from one side to the other. This will require a machine considerably larger, though the same blades will suffice; or it is found equally convenient to cause the blades, at the time they are cutting, to move over the cloth in any direction, but more especially from lift to lift.

Mr. Fryer also contemplated the finishing of the cloth
VOL. XXXVIII.

by the same machine which performed the shearing. Thus after the cloth has undergone the operation of shearing or cropping, in its passage down to the cylinder on which it is wound up, it is exposed to a current of steam thrown out from a horizontal tube at a number of small apertures, so as to give softness and pliability to the cloth; a brushing cylinder is next made to move against it, by which the remaining wool or fur is laid in one direction. It then passes between two polished metal cylinders, which are made hollow, and kept hot by the admission of steam or otherwise. These occasion a great pressure on the cloth, and dissipate all the water imbibed from the steam.

Rotatory Shearing-Machine.—A very complete machine for cropping cloth of any breadth was invented by Mr. Price, of Stroud, in Gloucestershire, and for which he obtained a patent in 1815. This machine shears or crops the cloth across the breadth, beginning at one end of the piece, and continuing regularly to the other. For this purpose, the cloth is conducted through the machine by the motion of rollers, and is drawn over a bed or support which lies beneath the stationary or fixed blade of the shears or croppers, (which answers to what is called the ledger-blade in the common shears,) so that the cloth passes between the bed and the stationary blade.

The moving blades of the shears are fixed on the circumference of a cylinder situated above the fixed blade, with its axis exactly parallel thereto, and capable of revolving by the power of machinery, so that the edges of the moving blades will be carried against and passed over the edge of the fixed blade, in order to cut away all the wool of the cloth which rises above the edge of the fixed blade. Several such moving blades are fixed upon the same cylinder, to act in succession against the fixed blade; and these moving blades are placed obliquely to the axis of the cylinder, or in such a manner as to form portions of spirals; but as all parts of the cutting edges are equidistant from the axis of the cylinder, it is manifest, that in the revolution of the cylinder, every part of each spiral edge is brought in succession into contact with the fixed blade, so that in its revolution it crops off all the wool, which by the progressive motion of the cloth over its bed is raised up against the fixed edge. The edges of the moving blades are placed at such a degree of obliquity to the axis of the cylinder, that at the same instant the end of one ceases to cut against the edge of the fixed blade, the following revolving blade will begin its action at the other end of the cylinder; therefore, by the time that any one of the revolving edges has passed over and made its cut against the whole length of the fixed blade, and is ready to quit it, the succeeding revolving edge is brought into action, and when this has passed, the next in succession begins, so as to keep up a continued action.

The cloth is stretched in width by a contrivance which he calls stretching-bands, to prevent it getting into folds or wrinkles, which would be injured by the shears, or make irregularities in the shearing. These stretching-bands are endless straps or bands, each of which is extended over two wheels. The bands have sharp pins projecting from them to prick into the lifts at the edges of the cloth, and the bands being so situated that one of them lies exactly beneath each lift, they will be caused to circulate round their respective wheels by the motion of the cloth. The stretching of the cloth is effected by the position of the wheels on which the bands circulate, the direction of the bands being slightly oblique to the lengthways of the cloth. The endless straps are so fitted into grooves or troughs, that they are firmly retained to move straight forwards in their oblique direction; and the direction of the obliquity is such, that the

bands are nearest together at that end where their pins take hold of the lifts of the cloth; but as the bands move forwards with the cloth, they recede from each other, and extend the cloth in breadth in consequence of their obliquity, which may be increased or diminished as is found necessary. The actual width between the two bands can also be regulated according to the width of the piece of cloth.

It is not usual to crop the lifts of the cloth, and indeed as the lifts are usually of thicker substance than the other parts of the cloth, they would bear up the fixed blade too high from the cloth to cut the nap quite close.

For this reason, the bed or support on which the cloth is cut is so constructed, that it can be adapted in length to the breadth of the piece of cloth between the lifts, in order that the cloth only may be supported or borne up to the edge of the fixed blade; whilst the lifts, being depressed or borne down below the level of the bed, (by thin slips of metal called guards,) will escape the action of cropping, and thereby remain with the long wool upon their surfaces. The bed by which the cloth is borne whilst it is cut is only a narrow ridge of metal, over which it passes, so as to be bent with a sudden curvature, and in this way, the nap can be cut more close and even than upon a flat bed or soft cushion. The operation of cutting is facilitated by a row of pieces of metal screwed to a strong bar, to form a straight edge, very similar to the cutting edge of the fixed blade, but thin and elastic; this edge is placed close to the elevated ridge of the bed, and presses the cloth gently down upon the bed immediately before it comes to the edge of the fixed blade, against which the nap is to be cut off; this elastic edge being placed on one side of the ridge, and the cutting edge of the lower blade on the other side, the cloth is only exposed for a very narrow space just where it comes to the cutting edge. By this means, the cloth can with safety be brought nearer to a level with the upper surface of the fixed blade, so as to shear it closer than could otherwise be done without endangering the cloth.

The ends of the ridge part of the bed are composed of a number of narrow plates of metal, accurately fitted together, and placed side by side in a mortise made in the end of the solid bed; their upper ends project out of the mortise so as to line with the elevated ridge, and form a continuation thereof; but there is a sliding piece in the bottom of the mortise on which they all bear, and the point of it is of a wedge form. By removing this wedge, any number of the moveable pieces may be let down, so as to diminish the length of the elevated part of the bed at pleasure, according to the breadth of the cloth. The whole of this machine is very well contrived to effect the desired object; it will be found fully described with drawings in the *Repertory of Arts*, vol. xxix. p. 65.

Frizing is an operation sometimes used in the finishing of woollen cloth: it consists in rolling up and entangling the fibres, which form the nap on the surface of the cloth into small knots or burs, which cover near the whole surface, so that the cloth appears covered with small grains, which almost touch each other.

This operation is of no utility to the cloth, and it is difficult to say for what reason it was ever practised at all. The French first introduced it, and it was so much the fashion many years ago, that no other cloth was thought comparable in beauty. At present it is but little used, except for foreign markets, where our cloth meets the French cloth, which is still prepared in this manner, but generally on the back-side of the cloth only.

The frizing is done by a simple machine, in which the cloth is drawn across a narrow table by means of rollers,

to give it a very slow progressive motion. The table is covered with a coarse strong cloth, and over the table is placed a heavy plank of wood, of the same size as the table. The lower side of this plank, which bears upon the cloth, is covered with an artificial stone, composed of coarse sand, which is stuck together into a solid mass by glue or other cement, and a small but rapid reciprocating motion is given to the plank by means of two cranks of very small radius. These cranks are formed at the tops of two vertical spindles, the upper ends of which are fitted in sockets at the ends of the fixed table, and the ends which project up a few inches above the surface of the table are received into sockets formed in each end of the moveable plank. The projecting parts of the spindles are not in straight lines with those parts which are fitted in the fixed collars at the ends of the table, but are slightly cranked; hence, if the spindles are turned round, they must communicate motion to the plank, and slide it over the cloth backwards and forwards; or rather they move it with a circular motion, causing every point and grain of sand cemented to the plank to describe a small circle upon the cloth. It is this action which gathers together the fibres of the nap, and entangles them into knots or grains, as before mentioned.

To put the two spindles in motion, each one has a trundle or lantern fixed on the middle part of it, and the lower end is received in a stationary socket. These lanterns are turned round by the teeth of two face-wheels, fixed upon an horizontal axis, which lies beneath the machine. By this means, both the spindles and cranks are turned round at the same time, and with a very rapid motion. The rollers which draw the cloth forwards are turned round slowly by a communication of wheel-work, and draw the piece of cloth through the machine, that is, across the frizing-table, so that every part is in turn subjected to the action of the sand cemented to the plank. The nap must be left long for that cloth which is intended to be frized, and the operation is repeated twice or three times. See some further particulars in our article *FRIZING*, vol. xv.

Brushing.—After being shorn for the last time, the cloth is brushed all over, to remove the loose cuttings. This operation is now commonly performed by a machine which has two horizontal drums, or cylinders, covered with hair-brushes on the circumference. The piece of cloth is conducted over a system of rollers to extend it and draw it slowly forwards: it is conducted over one of the brushing-cylinders, and under the other; and as they are kept in rapid motion by the machine, they brush over both sides of the cloth at the same time, and lay all the fibres one way.

Pressing.—This is the last finish to the cloth, and gives it a smooth and even surface. The piece of cloth is folded backwards and forwards at every yard, so as to form a pack on the board of a screw-press; and between every fold sheets of glazed paper are placed, so that no part of the surfaces of the cloth can come in contact; also at every twenty yards three hot iron plates are put in between the folds, the plates being laid side by side, so that they occupy the whole surface of the folds; and thin iron plates, which are not heated, are also put above and below the hot plates to moderate the heat. When the pack of cloth is properly folded, and the press contains a proper quantity, the screw is forced down to give a very severe pressure to the pack. The cloth remains in the press until the plates are quite cold; it is then taken out and folded again, so that the creases of the former folds will come opposite to the surfaces of the paper, in order to be pressed with other hot plates.

The heat tends to soften the fibres of the wool, and the pressure

WOOLLEN MANUFACTURE.

pressure against the glazed paper, whilst they are so softened, lays all the fibres flat and smooth, so that the cloth has a very glossy appearance, and feels smooth, like satin; but this high finish to the cloth is very objectionable, because the slightest shower of rain will take it away, and when the drops of rain only wet it in parts, the cloth will become spotted and disfigured. For this reason, in pressing superfine cloth, the plates are very slightly warmed, and the cloth has but little gloss given to it. The glazed paper is a thick kind of cartridge, which is prepared by glazing or rubbing it very forcibly with a flint, as it lies upon a hard metal table. This operation is done by a water-mill.

For coarser cloths, some manufacturers gloss them with a large hot iron: it is a hollow box, into which a red-hot heater is introduced. The cloth is spread out upon a large flat table, and extended by hooks. The iron box is suspended by a tackle from the ceiling, so that it can be hoisted over to the middle of the table, and then two men work it backwards and forwards over the whole surface of the cloth, by means of two long poles or handles, which are jointed to it at one end.

The cloth is now finished, and is packed up in bales of twenty or twenty-five pieces, in order to be transported. The bale is first inclosed in paper, and then in canvas, and closely compressed by the screw-press. Some manufacturers use the hydrostatic presses for this purpose.

In considering the processes of the woollen manufacture, as they were practised forty or fifty years ago, and comparing them with the present practices, we find great changes and improvements, but they are by no means carried to so great an extent as in the cotton manufacture. This is owing in a great degree to the circumstance that the manufacture of woollen cloth was rendered very perfect, as far as the goodness and beauty of the cloth was concerned, long before the improved system was begun; and there were great numbers of experienced and able workmen trained up for each process, who by habit and dexterity performed their work as well as it could be done by machinery. The reduction of labour, or the substitution of ordinary hands for experienced workmen, was in this case all that machinery of the most perfect kind could effect; both these were advantages to the public and the manufacturer, but were so directly opposite to the inclination and interest of the able workmen, that we find they have made greater and more effectual opposition to the introduction of improvements in the woollen than in any other of our great manufactures.

At various periods attempts have been made by the workmen to suppress machinery, and many mills have been destroyed. In July 1802, considerable riots took place in Wiltshire and Somersetshire, in consequence of an attempt to set up the machines called gig-mills. It was contended that this was the same machine which was prohibited by an ancient statute of Edward VI. The disputes ran so high, that the attention of parliament was called to the subject of the laws then existing for the regulation of the woollen manufacture, and a committee was appointed to investigate the policy of encouraging or regulating machinery. In consequence, all the prohibitions of machinery were suspended. The report of this committee contains the following remarks, some of which are applicable to other manufactures as well as the woollen.

The introduction of the gig-mill and other machines was opposed from an idea that it would throw a considerable number of hands out of work; and it was contended, that it was highly injurious to the quality and texture of the cloth. With respect to the actual effects of the gig-mill and shearing-frame on the cloth, the committee report that deci-

five evidence has been adduced before them by merchants and manufacturers of the greatest credit and experience, to prove that these machines, especially the gig-mill, when carefully employed, finish the cloth in the most perfect manner, and that manufacturers residing in parts of the country where the gig-mill is not used, frequently send their cloths to a distance to be dressed by it.

It also appeared in evidence, that alarms similar to the present had existed among workmen at the introduction of several of the machines which are now in general use. Such alarms have gradually subsided as prejudice died away; and the machines are now fully established, without, as it appears, impairing the comforts or lessening the numbers of workmen. The committee remark with much satisfaction, that in many instances in which it was apprehended that the introduction of particular machines would throw such a number of people out of employment as to occasion great distress, the result has been very different; for besides the occupations which the attendance on such machines has given rise to, a fresh demand for labour to an immense extent has arisen out of the increased sale of the article, in consequence of the cheapness and superior quality of the manufacture.

They approve the system of patents, by which the inventor of any new machine secures to himself the exclusive benefits of his discovery for fourteen years; and only, at the end of that term, they are thrown open to the public; this provides in most cases against the too sudden and general establishment of any invention, by which a number of workmen might at once be thrown out of employment.

They next observe, that if the principles on which the use of these particular machines is objected to were once admitted, it would be impossible to define the limits or to foresee the extent of their applications. If the parliament had acted on such principles fifty years ago, the woollen manufacture could never have attained to near its present extent. The rapid and prodigious increase of late years in all the manufactures and commerce of this country is universally known, as well as the effects of that increase on our revenue and national strength. In considering the immediate causes of that augmentation, it appears to the committee, that it is principally to be ascribed, under the favour of Providence, to the general spirit of enterprize and industry among a free and enlightened people, left to the unrestrained exercise of their talents in the employment of a vast capital, pushing to the utmost the principle of the division of labour, calling in all the resources of scientific research and mechanical ingenuity, and, finally, availing themselves of all the benefits to be derived from visiting foreign countries, not only for forming new and confirming old commercial connections, but for obtaining a personal knowledge of the wants, the taste, the habits, the discoveries and improvements, the productions and fabrics, of other civilized nations. Thus bringing home facts and suggestions, perfecting our existing manufactures, and adding new ones to our domestic stock; opening, at the same time, new markets for the product of our manufacturing and commercial industry, and qualifying ourselves for supplying them.

The committee declare it to be their opinion, that by these means alone, and above all by the effect of machinery in improving the quality and cheapening the fabrication of our various articles of export, notwithstanding a continually accumulating weight of taxes, and with all the necessities and comforts of life gradually increasing in price, (the effects of which on the wages of labour could not but be very considerable,) our commerce and manufactures have also been increasing in such a degree as to surpass the most sanguine calculations of the ablest political writers who have speculated

lated on the improvements of a future age. The exports of woollen goods at the time of this report, (1807,) amounted to six millions of pounds official, or nine millions of real value.

It appeared also to be an important consideration, of which we should never lose sight, that we are at this day surrounded by powerful and civilized nations, who are intent on cultivating their manufactures and pushing their commerce; and who are more eager to become our competitors in trade, from having witnessed the astonishing effect of our commercial prosperity. The attempts which have been made to carry our machines and implements over to foreign countries, and to tempt our artificers to settle in those countries, evince the importance of machinery, under the directions of men of approved skill, in constructing and using them. It is needless to remark how much these attempts would be favoured by our throwing any obstructions in the way of enterprise and ingenuity, and the free application of capital in this country; for any machines which should be prohibited here would infallibly find their way into foreign nations in a very short time.

Among the attempts to improve the woollen manufacture, we must not omit to notice the invention of Mr. Joseph Booth, for fabricating woollen cloth without spinning or weaving. This was effected by felting wool into a web by the aid of machinery, which operated mechanically upon a tissue of carded wool, to entangle and interlace the fabrics together. The inventor took a patent for this in 1793 or 1794, but before the time for the enrolment of the specification of his process, he obtained an act of parliament, the preamble of which states, that on account of the great importance of the art, and the danger of its being carried abroad to the injury of the staple manufacture of the kingdom, parliament had determined to keep the specification sealed; hence we are not able to give the details of this machinery.

We find these expectations have not been realized; for, although the process has been repeatedly tried on a large scale and in the most complete manner, it has been abandoned. Three large mills were established at Taunton and near Salisbury, by experienced woollen manufacturers of the west of England; another mill was converted to the purpose at Lewisham, in Kent; and the last mill was erected at Merton, in Surrey, the property of James Perry, esq. We learn from this gentleman, that he was able to manufacture cloth of a fine surface, and of a very even and regular substance, but it was rather deficient in strength, for want of the threads which form the substance of common cloth; and in respect to wear it was less durable than common cloth, as it did not long withstand brushing; otherwise the expence of the process, which was not one-fourth of the common process, would have brought it into general wear.

There has been a great number of other projects and patents for the improvement of different branches of the woollen manufacture; but as we have already noticed most of those which have come into use, we shall not enumerate any more of the unsuccessful attempts.

The machinery for manufacturing long combing-wool is described in the article WORSTED.

WOOLLEN *Nets*, in *Gardening*, a kind of nets employed as a protection in the setting of the fruit of different sorts of tender trees. See WOODEN *Frames*, &c.

WOOLLEY-WOOLLEY, in *Geography*, a town of Africa, in the kingdom of Yani.

WOOLLI, a kingdom of Africa, bounded by Walli

on the W., by the Gambia on the S., by the small river Walli on the N.W., by Bondou on the N.E., and on the E. by the Simbani wildernesses. The country every where rises into gentle acclivities, which are generally covered with extensive woods, and the towns are situated in the intermediate valleys. Each town is surrounded by a tract of cultivated land, the produce of which is thought to be sufficient for supplying the wants of the inhabitants; the soil appeared to Mr. Park to be every where fertile, except near the tops of the ridges, where the red iron-stone and stunted shrubs sufficiently marked the boundaries between fertility and barrenness. The chief productions are, cotton, tobacco, and esculent vegetables; all which are raised in the valleys, the rising grounds being appropriated to different sorts of corn. The capital is Madina, or Medina, signifying in the Arabic *city*. (See MEDINA.) The inhabitants are Mandingoes, (see MANDING,) who, like most of the Mandingo nations, are divided into two great sects, the Mahometans, who are called Bushreens, and the Pagans, who are denominated indiscriminately Kafirs, *i. e.* unbelievers, and Sonakies, *i. e.* men who drink strong liquors. The latter are the most numerous, and the government of the country is vested in them; for though the Bushreens are consulted in all matters of importance, they are not allowed to take any share in the executive government, which rests solely in the Manfa, or sovereign, and great officers of the state. Of these, the first in point of rank is the presumptive heir of the crown, called the Farbonna; and next to him are the Alkaidis, or provincial governors, who are more frequently styled Keamos. Then follow the two grand divisions of freemen and slaves, the Slatees being considered as the principal of the former; but in all classes great respect is paid to the authority of aged men. Park's Travels, vol. i.

WOOLLIMA, BA, a river of Africa, called also *Wonda*; which see.

WOOLLY-PASTINUM, in *Natural History*, a name given by the East Indians to a species of native red arsenic, or orpiment, found in that part of the world.

It is of a paler colour than the red orpiment of Germany.

WOOLMAN, JOHN, in *Biography*, a minister of the society of Friends in North America, chiefly remarkable as an early and faithful advocate of the rights of the enslaved Africans, was born at Northampton, in Burlington county, West New-Jersey, in the year 1720. From some memoirs of his life left by himself, it appears that he had strong impressions of religion in childhood, which being seconded by the care and admonition of pious parents, he arrived at manhood, after a struggle of some years with youthful levities, with a decidedly religious character. An incident which befel him when a child, and which he records as a proof of the early influence of divine grace on the mind, may be mentioned here, as connected also with his future character, and with the first development of those tender sympathies of the heart which, under the guidance of Christian principle, fitted him so eminently to espouse the cause of the oppressed negroes. Going on an errand to a neighbour's, he observed that a robin quitted her nest at his approach, and flew about in alarm for her young ones. He stood and threw stones at her, till being struck, she fell down dead. "At first," he says, "I was pleased with the exploit, but after a few minutes was seized with horror. I beheld her lying dead, and thought those young ones, for which she had been so careful, must now perish for want of their dam to nourish them: and after some painful considerations on the subject, I climbed up the tree, took all the young birds, and killed them, supposing that better than to leave them to pine

WOOLMAN.

away, and perish miserably. I then went on my errand, but for some hours could think of little else but the cruelties I had committed, and was much troubled. Thus He, whose tender mercies are over all his works, hath placed a principle in the human mind, which incites to exercise goodness towards every living creature: and this being singly attended to, people become tender-hearted and sympathizing, but being frequently and totally rejected, the mind becomes shut up in a contrary disposition." Of his opinions at one-and-twenty he writes thus: "I was early convinced in mind that true religion consisted in an inward life, wherein the heart doth love and reverence God the Creator, and learns to exercise true justice and goodness, not only toward all men, but also toward the brute creatures. I found no narrowness respecting sects and opinions, but believed that sincere, upright-hearted people in every society, who truly loved God, were accepted of him."

The right of every individual, of whatever colour, who has not offended against society, to liberty and the common gifts of providence, was consequently at this time an article of John Woolman's *religious creed*: and we shall see that he soon brought himself to act in consistency with his faith. The first occasion of trial occurred while he was yet in servitude; for he had engaged himself as clerk and assistant to a shop-keeper at a place called Mount-Holly. His employer parted with a negress, and desired Woolman to write out a bill of sale for her. "The thing," says he, "was sudden, and although the thought of writing an instrument of slavery for one of my fellow-creatures felt uneasy, yet I remembered that I was hired by the year, that it was my master who directed me to do it, and that it was an elderly man, a member of our society, who bought her. So through weakness I gave way and wrote; but at the execution of it I was so afflicted in my mind, that I said before my master and the friends, that I believed slave-keeping to be a practice 'inconsistent with the Christian religion.' This in some degree abated my uneasiness; yet as often as I reflected seriously upon it, I thought I should have been clearer if I had desired to be excused from it, 'as a thing against my conscience;' for such it was." Accordingly, on the next occasion he took this second step. "A young man of our society," he proceeds, "spoke to me to write a conveyance of a slave to him, he having lately taken a negro into his house. I told him I was not easy to write it: for though many of our meeting and in other places kept slaves, I still believed the practice was not right." Other cases followed, in which being employed (as it appears for an adequate fee) to write the will of a neighbour or a friend, he uniformly refused to be accessory to their bequeathing as property the persons of his fellow-men. "Deep-rooted customs," he observes, "though wrong, are not easily altered; but it is the duty of all to be 'firm in that' which they certainly know is 'right for them.' A charitable benevolent man, well acquainted with a negro, may, I believe, under some circumstances, keep him in his family as a servant for no other motive than the negro's good. But man, as man, knows not what shall be after him, nor hath assurance that his children will attain to that perfection in wisdom and goodness necessary rightly to exercise such power," viz. as that of the owner over his slave. As the first-fruits of this firmness, and which no doubt were highly grateful, he relates instances in which his refusal, and the reasons he gave for it, procured the freedom in lieu of the transmission of the slaves in question.

Having been acknowledged by his friends in the capacity of a minister of the gospel, he made some journeys in the exercise of his gift, which served to give him a further insight

into the condition of the negroes on that continent, and further excited his attention to the then practice of the society of friends, in common with others, of holding them in bondage, and even of buying them. In the year 1746 he passed through Virginia, Maryland, and Carolina, of which he writes as follows: "Two things were remarkable to me in this journey: first, in regard to my entertainment, when I ate, drank, and lodged at free-cost with people who lived in ease on the hard labour of their slaves, I felt uneasy; and as my mind was inward to the Lord, I found, from place to place, this uneasiness return upon me at times through the whole visit. Where the masters bore a good share of the burthen, and lived frugally, so that their servants were well provided for, and their labour moderate, I felt more easy; but where they lived in a costly way, and laid heavy burthens on their slaves, my exercise (trouble of mind) was often great, and I frequently had conversation with them in private concerning it. Secondly, this trade of importing slaves from their native country being much encouraged among them, and the white people and their children to generally living without much labour, was frequently the subject of my serious thoughts. And I saw in these southern provinces so many vices and corruptions, increased by this trade and this way of life, that it appeared to me 'as a gloom over the land;' and though now many willingly run into it, yet in future the consequence will be grievous to posterity. I express it as it hath appeared to me, not once nor twice, but as a matter fixed on my mind."

It is probable that the inhabitants of the southern provinces of North America now see pretty clearly that their negro population, without consummate prudence, as well as great kindness in the management of them, are likely one day to justify these anticipations.

On his return from the above-mentioned journey, he committed to paper his sentiments on slave-keeping, and after the MS. had lain long by him, it was published, with the approbation and at the expence of his friends, who began (in Pennsylvania and the Jerseys at least) to be more generally influenced by the humane and Christian views of Woolman, Benezet, and others on this subject. It was entitled "Some Considerations on the keeping of Negroes;" and in 1762 was followed by a "Second Part," the expence of which he preferred to take upon himself, for a reason which evinces his strict regard to justice. He considered that many, who did not yet see the evil of the practice, nor approve of his writings against it, were contributors to the general fund of the society, out of which the cause was proposed to be defrayed.

Some other reflections, written in 1757, while he was on a journey among slave-holders, and recorded in his "Memoir," are forcibly descriptive of his views and feelings.

The necessary brevity of this article will permit only a general account of John Woolman's labours in the cause of humanity. From private conferences with the holders of slaves, he proceeded to public addresses to the society in their meetings for discipline: and when at length the principle of the unlawfulness to Christians of this degrading practice had been generally recognized among them, he united other members with himself in paying visits to such of the society, within his sphere of action, as required the stimulus of remonstrances to induce them to comply with the sense of their brethren on this subject. These proceedings were prosecuted through several journeys; in which at one time the religious welfare in a more general sense, at another the right conduct in this particular of his fellow-members, engaged his attention. He did not live to see the completion of his wish as it related to the society; for it was not

till the year 1787 that the last slave disappeared from among them. But the near approach of this conflagration was witnessed by his coadjutor, Anthony Benezet, who died in 1784, whose fame has spread wider than Woolman's, because his opportunities were more extensive, who lived for the cause throughout Europe, and carried its successful plea from the narrow limits of the society of Friends into the world at large. Of this excellent man, whose biography escaped the early part of this work, it may not be too late here to record in brief,—that he was born at St. Quintin, in Picardy, of a respectable family, in 1713; that he was carried by his father, who fled from the persecutions which fell upon the Huguenots, to London, and there formed for mercantile pursuits; that upon removing to Philadelphia with his family in 1731, having now entered into the society of Friends, he devoted his life, upon principle, first to the education of youth in useful knowledge and the Christian faith, and ultimately to the noblest toils of humanity. But to return to our present subject: in the year 1772, John Woolman, believing it his duty to pay a religious visit to the friends in England, embarked for that purpose at Chester, on the Delaware, and arrived at London in time to attend their yearly meeting. After it he travelled, exercising his ministry among his friends, through several counties, as far as York. Here, at a large quarterly meeting, he once more pleaded for the negroes, endeavouring, and probably with effect, to engage the support of those present to the cause of humanity: soon after which he was seized with the small-pox. During a severe struggle with this disease, he manifested great patience and humility, with a firm faith in the Redeemer: and nature sinking in the conflict, he expired in peace in his fifty-second year.

As a preacher, we hear not of his eloquence nor of his learning, except, says one of the respectable friends who has favoured us with the documents of this article, “in heart-knowledge, and in the school of Christ;” but in life, he was a bright example of the integrity, meekness, charity, and beneficence which in that school alone are to be acquired; and his memory for his works’ sake is blessed. Memoir of John Woolman, chiefly extracted from a Journal of his Life and Writings, London, 1815.

WOOLPER’S CREEK, in *Geography*, a river of Kentucky, which runs into the Ohio, N. lat. 38° 53'. W. long. 85° 7'.

WOOLPIT, a village of England, in the county of Suffolk; 8 miles E. of Bury St. Edmunds.

WOOLSTANTON, a village of England, in Staffordshire; 2 miles N. of Newcastle-under-Line.

WOOL-STAPLE, denotes a city or town where wool used to be sold. See STAPLE.

WOOLSTED. See WORSTED.

WOOLSTON, THOMAS, in *Biography*, an English divine, was born in 1669 at Northampton, and admitted in 1685 of Sidney college, Cambridge, where he was distinguished by his diligence and regularity. He was elected fellow of his college, took orders, preached with approbation, and was esteemed for his learning and piety. In his exercises for the degree of B.D. he maintained “the exact fitness of the time in which Christ was manifested in the flesh,” in a discourse which was well received. But his temper being naturally enthusiastic, and perusing the works of Origen, he indulged a great fondness for allegorical interpretations of scripture, which afterwards led him into a variety of singular and extravagant opinions. He began in 1705 with “The old Apology for the Truth of the Christian Religion against the Jews and Gentiles revived,” maintaining that all the actions of Moses were

typical of Christ, and of his church; and the book was issued from the university press. Woolston remained in college till the year 1720, when he went to London, and published a Latin dissertation concerning the supposed epistle of Pontius Pilate to Tiberius, relative to Jesus Christ. In the same year he also published two Latin epistles, addressed to Whitty, Waterland, Whiston, and others: “Circa Fidem vere Orthodoxam et Scripturarum Interpretationem,” defending Origen’s allegorical interpretation of scripture. His deviation from the established faith was more apparent in his inquiry, “Whether the people called Quakers do not the nearest of any other sect in religion resemble the primitive Christians in principles and practice?” Blending sarcasm with argument, he now seemed to indulge a spirit of animosity against the clergy. Declining at the same time to reside at college, he was deprived of his fellowship in 1721. In his “Four Free Gifts to the Clergy,” he denominated them “hireling priests,” and “ministers of the letter.” Although he might be suspected, he was not yet chargeable with historical incredulity; for in 1726 he published “A Defence of the Miracle of the Thundering Legion against Mr. Moyle.” At length he engaged in the controversy between Anthony Collins and his opponents, and published “The Moderator between an Infidel and an Apostate,” and “Two Supplements,” in which he not only contended for mystical interpretations of the miracles of Christ, but maintained that they were never actually wrought. Considered as an avowed enemy to the Christian religion, a prosecution was instituted against him by the attorney-general, but stayed by the interposition of Whiston, and some other advocates of toleration. Notwithstanding this lenity, he proceeded in publishing “Six Discourses on the Miracles,” and two “Defences of the Discourses,” in which, blending ridicule and buffoonery with argument, he maintained his offensive opinions. This pertinacity and rudeness prejudiced believers in the divine mission of Christ against him; replies issued from the press; but as he again became amenable to the law, he was tried at Guildhall before lord chief justice Raymond, when, after many arguments for and against him, he was found guilty, and sentenced to a year’s imprisonment, and a fine of 100*l*. Unable to pay his fine, he resided within the rules of the King’s Bench, and subsisted by an annual allowance granted to him by his brother, and the contributions of some learned and liberal friends, who vindicated his intentions, whilst they disapproved his enthusiasm and fanaticism. Among these were some, and particularly Dr. S. Clarke, who condemned every species or semblance of religious persecution, and who endeavoured to procure his release; but they could not prevail upon him to stipulate that he would not persevere in publishing his peculiar opinions. But death gave him that release, which his friends could not obtain for him; as he was carried off by an epidemic disease, within four days after his seizure, in January 1732–3. Not long before he expired, he said, “This is a struggle which all men must go through, and which I bear, not only patiently, but willingly.” His moral character is said to have been unimpeachable, and his head was thought to have been more disordered than his heart. Biog. Brit.

WOOLWICH, in *Geography*, a market-town and parish in the hundred of Blackheath, lath of Sutton-at-Hone, and county of Kent, England, is situated on the S. bank of the Thames, 8 miles E. from London. The etymology of Woolwich, a name very variously written at different periods, is uncertain: according to Hasted, in his “History of Kent,” one of the ancient names, Hulviz, signified the “dwelling on the creek.” The parish comprehends about

about 700 acres, of which above one-half, however, lie on the opposite bank of the Thames, in the county of Essex, and consists of marsh-land, on which stood formerly a few houses, and a chapel of ease. The manor of Woolwich is subordinate to the royal manor of Eltham. The town consists chiefly of one narrow irregular street, confined between the rising land and the river; but several other streets, rows, and lanes, are connected with it. The church, a spacious brick building, consists of a nave, chancel, and aisles. It is situated on an eminence overlooking the town and the dock-yard, and was completed in 1740. Besides this building, Woolwich contains several different dissenting meeting-houses. The principal charitable establishments are an alms-house and two schools. Woolwich was originally but a small place, inhabited by fishermen, and is indebted for its importance to the establishment of a royal dock there in the reign of Henry VIII. Since that time, it has gradually arrived at its present augmented state; but particularly since the establishment there of the head-quarters of the artillery and the royal arsenal; by which means the population within the last hundred years has increased six-fold. The precise period of the establishment of the dock-yard is uncertain: it appears, however, that the *Harry Grace de Dieu*, of 1000 tons, was built there in 1512. This celebrated ship is stated to have been in length 128 feet, and in breadth 48 feet: she had three flush decks, a fore-castle, half-deck, quarter-deck, and round-house, and carried 176 pieces of ordnance: she had eleven anchors, the largest of which weighed 440 lbs. In its present enlarged state, the yard extends about five furlongs along the river by one furlong in breadth. It comprehends two dry docks, several slips, three mast-ponds, a smith's-shop and forges for making anchors, a model-loft, store-houses, sheds, dwellings for various officers, and all other requisite buildings. The whole is under the immediate inspection of the navy board, but conducted by several resident officers. The number of artificers and labourers employed during peace is about 1500; but in war-time it rises towards 4000. Between the dock-yard and the royal arsenal, formerly called the Warren, is the rope-walk, 400 yards in length. The military and civil branches of the office of ordnance have been established at Woolwich since the accession of George I. In the time of peace, this arsenal is the great repository of naval ordnance, where the guns of most of the ships of war are laid up there in order. The repository contains also an extensive collection of military machines and models. The arsenal, comprehending about sixty acres of ground, contains, with other buildings, the foundery, and the late military academy, which was erected by sir John Vanbrugh. The foundery is provided with several furnaces, the largest of which will melt about seventeen tons of metal at once. It contains also machinery for boring brass cannon, as they are improperly called, for they are composed of copper and tin instead of zinc. In the adjoining laboratory, bombs, carcasses, cartridges, &c. for the navy and army, are prepared. The number of persons employed in the arsenal during war is about 300, exclusive of the convicts belonging to the hulks or prison-ships lying in the river. The military academy, although founded in 1719, was not finally arranged till 1741, and has been fortunate in possessing, in the mathematical chairs, the eminent professors Derham, Simpson, and Hutton. Besides the mathematical professors, here are masters in chemistry, fortification, arithmetic, French, drawing, fencing, &c. The number of pupils or cadets, destined for the two corps of artillery and royal engineers, has been lately about 300. To provide necessary accommodation, with offices, &c. a new edifice was con-

structed and opened in 1806, about a mile S. from the town, on the upper part of the common. It is built in the castellated form, from designs by Mr. James Wyatt. The principal front facing the N. extends above 200 yards. The expense of the structure is estimated at not less than 150,000*l.* The establishment is appropriated to the senior class of the cadets, the junior being for the present fixed at Black-Water in Hampshire. Between this new academy and the town are extensive ranges of barracks, &c. for the royal artillery, horse and foot, which has increased during the late war beyond all former example.

The population of Woolwich, in the return of 1800, was stated at 9826, exclusive of the military, inhabiting 1362 houses; but the number was probably under-rated; for in the return of 1811, the inhabitants are stated to be 17,054, and the houses 2487. Woolwich-common unites with the extensive plain of Blackheath on the S., which gives name to the hundred. At its eastern extremity rises Shooter's-hill, which commands extensive and interesting prospects in all directions. The view from it of London, the Thames, and the shipping, is peculiarly impressive. Over this hill passed the great Roman road from the E. coast of Kent, through *Durovernum*, now Canterbury, and *Durobriva*, Rochester, to London. Its course is nearly pursued by the present road from Shooter's-hill, for eight miles, to a place beyond Dartford.—*Beauties of England, Kent*, by E. W. Brayley, 8vo. 1806.

WOOLWICH, a township of New Jersey, in the county of Gloucester, with 3063 inhabitants; 10 miles S.E. of Philadelphia.—Also, a township of the province of Maine, containing 1050 inhabitants, on the E. side of the Kennebec; 16 miles N.E. of Brunswick.

WOOL-WINDERS are persons employed in winding up fleeces or wool into bundles to be packed, and sold by weight. Persons winding and selling deceitful wool, shall forfeit for every fleece 6*d.* These are sworn to do it truly between the owner and the merchant. 8 Hen. VI. cap. 22. 23 Hen. VIII. cap. 17.

WOORLA, in *Geography*, a town of Hindoostan, in Visapour; 16 miles N. of Merritch.

WOOTAMALLY, a town of Hindoostan, in Madura; 15 miles S.W. of Coilpetta.

WOOTTON, JOHN, in *Biography*, an eminent, though not very able, painter of landscape and animals, who flourished in England about 1720. He was a pupil of John Wyck, and was much employed in the portraits of horses and dogs, and in painting the sports of the field, particularly fox-hunting; upon which subject there are seven pictures of his engraved by Canot. Once at least he attempted (but he did not frequently repeat the attempt) to portray a battle, and his subject was that of Culloden at the time of the rout of the rebel army. It has been engraved by Baron, though it is but an indifferent performance. He died in 1765. He had been successful in the pursuit of his art, for he was enabled by its proceeds to build a house in Cavendish-square, where he lived, and had painted it with taste, according to Walpole, who praises his works ridiculously. His pieces, he says, were high, forty guineas for a single horse the size of life, and twenty if smaller.

WOOTTON-BASSET, in *Geography*, a borough and market-town of Wiltshire, England, is situated near the northern extremity of the county, at the distance of 36 miles N. by W. from Salisbury, and 89 miles W. from London. It consists chiefly of one principal street, about half a mile in length. The houses are mostly constructed of brick with thatched roofs. Two representatives have been regularly deputed from this town to serve in parliament

ment since the 25th of the reign of Henry VI. They are elected by the inhabitant householders legally settled there, and paying scot and lot. The corporation is composed of a mayor, two aldermen, and twelve burgesses. The market-day is Tuesday, weekly; and there are also six fairs annually. In the centre of the town are a market-house and shambles; and near this is the town-hall, in which a machine, called a "cucking or ducking-stool," formerly used for the punishment of female scolds, was lately preserved. The church is an old building dedicated to St. Bartholomew, but it is not remarkable for beauty of architecture, nor does it contain any monument or inscription worthy of notice.

According to the population returns of 1811, the borough and parish contained 321 houses, and 1390 inhabitants, who formerly carried on a considerable trade in broad-cloths; but there is now no staple manufactory of any sort, though some attempts have been lately made to introduce the business of rope-making and sack-making. In this parish are two free-schools and a Sunday school. The former were founded and endowed by the earl of Clarendon, one of them for twelve boys, and the other for twelve girls.

At the time of the Conquest, this place was called simply 'Wodeton.' It was then the property of Milo Crispin; but in less than a century afterwards it was possessed by the Bassetts of Wycomb, a branch of the noble family of the Bassetts of Drayton. The present proprietor is the earl of Clarendon. The ancient manor-house, which stands on the summit of a considerable eminence, is now converted into a farm-house, whence the eye surveys a very extensive prospect into Somersetshire, Gloucestershire, &c. A variety of curious conical stones, resembling small fir-apples, have been dug up in different spots around the town, imbedded in a sort of blue marly stone.

Liddiard-Tregooze, or Lydiard-Tregose, is a village and parish, situated at the distance of three miles north-east from Wootton-Basset. According to the population returns of 1811, the parish contains 95 houses, and 613 inhabitants.

The church, an ancient structure, is divided into a nave, two side aisles, and a chancel, with a square tower at the west end, surmounted by an open balustrade and angular pinnacles. The church contains several interesting monuments of the St. John family; also a very curious genealogical table with arms, &c.

Adjoining to the church is Liddiard-park, the seat of lord Bolingbroke. The attached grounds are extensive, and contain many large clumps of trees, among which are a great number of old oaks.—*Beauties of England and Wales, Wiltshire, by J. Britton, 1815.*

WOOTZ, in *Metallurgy*, a metal extracted from an ore of iron in the East Indies, the nature of which is not known at present in Europe. Wootz is highly esteemed by the natives of India, and applied to various purposes in the arts.

Dr. Scott gave the following account of its properties, in a letter to the president of Bombay:—"Wootz admits of a harder temper than any thing known in that part of India. It is employed for covering that part of gun-locks against which the flint strikes. It is used for cutting iron on a lathe, for cutting stones, and for chisels; also for making files and saws, and for every purpose where excessive hardness is necessary: it cannot, however, bear any thing beyond a slight red heat, which makes it work very tediously in the hands of the smith. It has a still greater inconvenience or defect, that of not being welded with iron or steel, to which, therefore, it is only joined by screws and

other contrivances." Dr. Scott observes farther, that when wootz is heated above a light red heat, part of the mass seems to run, and the whole is soft, as if it consisted of metals of different degrees of fusibility. The working with wootz is so difficult, that it is a separate art from that of forging iron. The magnetical power can only be imperfectly communicated to it. Specimens of wootz sent from India were examined by Dr. George Pearson, who states in the *Phil. Transf.* vol. xcvi., that they were in the form of round cakes, about five inches in diameter and one thick, each of which weighed more than two pounds. The cake had almost been cut through, so as to divide it into two nearly equal parts. It was externally of a dull black colour, the surface was smooth, the cut part was also smooth, and, excepting a few small holes, the texture appeared to be uniform. No indentation could be made in it by blows with a heavy hammer, nor was it broken by blows that might have broken a like piece of steel. Fire was elicited on collision with flint. It possessed the hardness of some kinds of crude iron, but did not effectually resist the file, like highly tempered steel, and many kinds of crude iron. It admitted a polish equal to the best steel. The wootz-filings were attracted by the magnet like common iron-filings. When broken, it exhibited the fracture and colour of a rather open-grained steel. It was tasteless and inodorous. Its specific gravity in different states, as given by Dr. Pearson, ranges from 7.2 to about 7.7, which is nearly the same as steel. From the properties of this substance, Dr. Pearson concludes, that wootz approaches nearer to the state of steel than raw iron, although it possesses some of the properties of this last substance. It is not to be referred to that kind of steel in which there is either an excess or deficiency of carbon, but it contains something besides carbon and iron, otherwise it would be common steel. The solution in nitrous and dilute sulphuric acid contained only oxyd of iron, and the residue of carbonaceous matter, as in common steel. Hence, says Dr. Pearson, it is obvious to suspect, that wootz contains oxygen, either equally united with every part of the mass, or united with a portion of iron to compose oxyd, which is diffused through the mass. To this circumstance, Dr. Pearson seems inclined to attribute the smaller quantity of hydrogen gas given out during solution, than is afforded by common steel, and to account for its partial fusibility and difficult malleability, and may be the reason of its taking a fine edge or polish. The oxyd is not perhaps equally diffused; hence the wootz is not quite uniform in its texture and hardness until it has been remelted. The proportion of oxygen in wootz, says Dr. Pearson, must, however, be very small, otherwise it would not possess so much strength, and break with so much difficulty. The oozing out of matter when fused is analogous to what appears on refining raw iron. Although no account is given by Dr. Scott of the process for making wootz, we may without much risk conclude, that it is made directly from the ore, and consequently that it has never been in the state of wrought iron, for the cake is evidently a mass which has been fused, and appears to have been cut almost quite through while white hot at the place where wootz is manufactured. The particular uses to which wootz may be applied are to be inferred from the preceding account of its properties and composition; and may be proved by an extensive trial of it in all the arts which require iron. See *Phil. Transf.* vol. xcvi.

WOPANKEN, in *Geography*, a town of Prussia, in the province of Bartenland; 2 miles E. of Bartenstein.

WOPELBACH, a river of Osnabruck, which runs into the Dalcke, 2 miles N. of Weidenbruck.

WORADA,

WORADA, a country of Africa, of an oval form, about 90 miles in circumference, S. of Konkadoo.

WORANY, a town of Lithuania; 28 miles S. of Troki.

WORBIS, or **STADT WORBIS**, a town of Westphalia, in the territory of Eichsfeld, on the Wipper; 8 miles S.S.E. of Duderstadt.

WORBIS, *Breiten*, a town of Westphalia, in the territory of Eichsfeld; 9 miles S.E. of Duderstadt.

WORBIS, *Kirch*, a town of Westphalia, in the territory of Eichsfeld; 8 miles S.S.E. of Duderstadt.

WORBITZ, a town of Bohemia, in the circle of Czaflau; 10 miles S. of Czaflau.

WORBITZ See, a lake of the Ucker Mark of Brandenburg, near Joachimthal; 28 miles N.N.E. of Berlin.

WORBSTADT, a town of France, in the department of Mont Tonnerre; 10 miles S.S.W. of Mentz.

WORCESTER, the capital city of a county of its own name, in the W. of England, situated in N. lat. $52^{\circ} 10'$, and W. long. $2^{\circ} 00'$; distant 26 miles N. from Gloucester, 27 S.W. from Birmingham, 30 E. by N. from Hereford, and 111 W.N.W. from London. The inhabitants in 1811 were, according to the returns made to parliament, 5953 males, and 7861 females, in all 13,814, and the houses 2527.

Historical Events.—Worcester is a place of high antiquity, as implied by the latter part of the name, indicating that the original town occupied the position of a Roman station: its proper name under those people, however, has not yet been ascertained. Camden indeed conceives it to be the *Branonium* of Antoninus' Itinerary, the same with the *Branogenium* of Ptolemy; but that town is placed by Horsley at Ludlow, more to the N.W., on the S. border of Shropshire. Nennius, who wrote in the beginning of the 7th century, points out Worcester by the British names *Caer-Guorangan* and *Caer-Guorcon*. By the Saxons it was called *Weogareceaster*, or *Wegeorna-ceaster*, from which came *Wigornia*, the Latin name still in use. In the Domesday-book it is called *Wirccestre*. The diocese of Worcester was founded by Ethelred, king of Mercia, about 680, the first bishop nominated being Tatfrith; but dying before consecration, the first who filled the episcopal chair was Bosel, a learned man from the celebrated monastery of St. Hilda, at Whitby in Yorkshire. St. Egwin, the third bishop, who was appointed in 693, was the founder of the abbey at Evesham. Mildred was nominated in 744. The 17th prelate was the famous St. Dunstan, who was appointed in 957. St. Wulfstan II., appointed in 1062, was the founder of the present cathedral. Adam de Orleton, bishop in 1327, is supposed to have prompted the murder of Edward II. by the equivocal answer he gave when consulted on the project: "*Edwardum occidere nolite timere bonum est.*" The 60th bishop, nominated to Worcester in 1521, was the celebrated Julius de Medicis, a cardinal, and afterwards pope Clement VII. His successor, Jerome de Ghinucci, also an Italian, was deprived at the Reformation, and, in 1535, was succeeded by Hugh Latimer, who suffered for his Protestant profession, under queen Mary, in 1555. John Prideaux, the 84th prelate, appointed in 1641, was dismissed during the interregnum, his bishopric sequestered, and himself allowed four shillings and sixpence *per week* for his maintenance. The eminent scholar Stillingfleet filled the see from 1689 to 1699. In 1717, the see was filled by John Hough. (See his biographical article.) The learned bishop Hurd, appointed in 1781, was succeeded in 1799 by the present prelate, bishop Cornwall. The revenues of the see

VOL. XXXVIII.

were, in 1699, fixed at 1302*l.* 15*s.* 4½*d.*; but now supposed to exceed 3000*l.* The see has possessed one pope, four saints, seven high-treasurers of England, eleven archbishops, besides chancellors of the kingdom, and other great officers of the state. Few places, perhaps, have suffered more than Worcester by the intestine broils of the country, and by casual disasters. Ruined by the Danes about the year 894, it was rebuilt by Ethelred and Ethelfleda; but the inhabitants refusing to pay the tax called danegelt, the city was again laid waste by Hardicanute. Again restored, it suffered severely during the contest between king Stephen and the empress Maud, as well as by a fire, from which the walls of the cathedral alone were preserved. Taking the part of Lewis, the dauphin of France, against king John, the king's troops exercised every tyrannical severity on the inhabitants; the church was plundered, and a heavy sum exacted from the clergy. John was nevertheless interred in the cathedral in 1216. It was in Worcester that, previously to the battle of Evesham, young Edward raised the standard of loyalty for his father, Henry III. After the accession of Henry VII. several citizens were beheaded, and a fine of 500 marks was levied on the city. In 1642 Worcester witnessed the sanguinary contest which terminated so fatally for the affairs of Charles I. (See CHARLES.) In 1646, the city surrendered by capitulation to the parliament's army, having been the first city in England to declare for the crown, and the last which held out in its defence. In 1651 happened the second battle of Worcester under Charles II.; a battle which decided the destructive and vindictive controversy between the royalists and the parliamentary party, by which the latter obtained a complete ascendancy; and the king himself escaped with difficulty out of the country. To preserve the memory of this success, "the lord-general Cromwell, on the 18th of September 1651," says Leach, in his Diurnal, "with many officers of the army, was at Woollidge, at the launching of a gallant new frigate of the states, carrying three-score peeces of ordnance, and called her name Worcester."

Present State.—Worcester is distinguished among the provincial towns of England for its resemblance, in various respects, to the metropolis. It is described to be well built, well paved, and well lighted. It consists principally of one great street running from N. to S., and terminating at the cathedral; also thirteen other collateral streets, besides lanes of inferior dimensions. The circuit of the city exceeds three miles and a half. The Severn, bathing the western side, and carrying vessels of considerable burthen, is of great utility in facilitating the commerce to and from, as well as the requisite supplies of the city. On it, passage-boats sail up as far as Shrewsbury, and down to Gloucester and Bristol. The buildings now extend beyond the ancient limits, which may, however, still be traced; the old wall, according to a plan made before the civil wars, was in extent 11,650 paces; but this wall, after the last battle of Worcester, was almost wholly destroyed. The castle was erected by Urfo of Abitoth about 1088. The area, now called the College-green, was, in the Norman times, the outer ward of that castle, behind which to the S. was the inner ward, or fortrefs itself. A gaol for the retention of the prisoners of the county is all that now remains of the castle, on the spot where the kings of England formerly kept their court. A steep artificial mount, on which probably stood the keep of the fortrefs, is a prominent object; the surrounding ditch and rampart may also be easily traced.

Cathedral.—The original cathedral of Worcester was founded in 680; but in 969 its revenues were transferred

to the monastery of St. Mary, an establishment of the beginning of the eighth century. The church of this monastery being unsuitable to its novel application, another cathedral was erected and consecrated by St. Oswald, the bishop, in 983. Being ruined by Hardicanute in 1041, the foundation of a new cathedral was laid in 1084, by bishop Wulfstan II.; and in 1089 he finished it, together with the monastery, and called the same *Monasterium St. Marie in Cryptis*. The original plan of this church seems to have been a simple cross, the entrance being at the west end of the present choir, which occupies the place of the ancient nave. This ancient structure had probably a central or principal tower; as it is recorded that the *new* tower fell down in 1175, and two smaller ones were destroyed by a storm in 1222. The antiquity of this part of the edifice is particularly apparent from the crypt or undercroft, which extends under the choir and its aisles. This is a curious and interesting part of the fabric. Twice severely injured by fire, in 1113 and in 1202, the cathedral was re-consecrated in 1218, by bishop Silvester, in the presence of Henry III. and his court. Six years afterwards the foundation of an additional work, the present nave, was laid by bishop William de Bloys, in which is displayed the skill of the architect, in adapting the new parts to the former structure. The stone-vaulting of the edifice was begun by bishop Cobham in 1327, and the whole was finished in 1357. The beautiful central tower was constructed in 1374. Worcester cathedral is in the exterior extremely plain, and its attractions consist principally in the height, space, and the lightness of its architecture, to which the lofty pinnacles, rising from every termination of the building, as well as from the tower, not a little contribute. The external length, including buttresses, is 426 feet; the internal, 394: that of the nave, from the front to the west transept, 180; of the choir, including the organ-loft, 120; of the Lady-chapel, 60; of the west cross or transept, 128; and of the east transept, 120 feet. The nave is separated from the aisles by ten clustered columns on each side, supporting three ranges of pointed arches; an arrangement also carried on through the choir. A stone pulpit, originally placed near the west end of the nave, is now fixed at the north side of the choir. It is of an octagonal form, ornamented with emblematic sculpture, and surmounted by a canopy.

Worcester cathedral has, like many other edifices of the same nature, been a great sufferer by the lapse of time, and by the various modes of repair adopted at different periods. It now scarcely contains one arris or moulding, as originally constructed. Roman cornices now occupy the place of battlements; buttresses are pannelled in various heterogeneous ways; pinnacles have been restored after the Grecian school; windows formed without ramifications or cusps, and filled with modern stained glass, destitute of subject or design; Roman arches resting on entablatures, to support or strengthen the transepts; Roman squares with leaves, instead of proper bases to regular clustered pillars. Indeed this edifice affords a curious, but not a very pleasing, display of heterogeneous parts and styles.

Of the numerous monuments contained in the cathedral, a few only can be noticed in this work. Between the pulpit and the communion-table, in the midst of the choir, is placed the altar-tomb of king John, who died in 1216. On it is extended his effigy. The inscription, "Johannes Rex Angliæ," is now almost illegible. The figure, as large as life, has in the right-hand a sceptre, and in the left a sword, with its point in the mouth of a lion couchant at the feet. On each side, on a level with the pavement, are small figures of bishops Oswald and Wulfstan. It had long

been imagined that this monument was merely an honorary cenotaph, while the body of John really lay in the Lady-chapel; but by an investigation in 1797, the contrary was ascertained. Removing the effigy and stone on which it rested, the interior of the monument was laid open. Between two brick walls, and under some elm boards, lay a stone coffin containing the royal corpse. The body had evidently been deranged at some former period; but many of the parts were very perfect. Instead of the crown, however, as shewn in the effigy, the head had been invested with the hood of a monk's cowl. The body had been enveloped in an embroidered robe, seemingly of crimson damask. The coffin rested on the pavement of the choir, and the original cover was the stone on which the effigy is sculptured. On the right-hand of the communion-table, occupying one of the arcades between the choir and the fourth aisle, stands the celebrated monumental chapel or chantry of Arthur, eldest son of Henry VII., and elder brother of Henry VIII. This chapel, of an oblong form, is richly ornamented on the north, west, and south sides, by open screen-work; the pillars adorned with a number of small statues, with shields, roses, and other figures emblematic of the houses of York and Lancaster, whose contending claims to the English throne were united in that young prince, who died in 1502, in the 17th year of his age. Against the east end was placed an altar, behind which was a wall ornamented with five figures; in the centre the Saviour, on the right-hand two kings in their robes, and on the left another similar king, and a warrior in armour. Over the statues are richly-wrought canopies. To preserve those figures from destruction, they had been covered over with plaster, probably in the reign of Elizabeth, and remained thus unknown until November 1788, when the plaster being removed, they were once more laid open to view. The tomb of prince Arthur is of marble, with the arms of England and France quartered, painted on the sides; round the edge of the cover is an inscription in English.

Worcester cathedral contains also the monument of the celebrated judge Littleton, the father of English law, a justice of the common pleas under Edward IV., who died in 1481. Of more modern sepulchral monuments it will be sufficient to mention those of bishops Hough, Maddox, and Johnson, not only for the eminent names they commemorate, but as distinguished examples of modern sculpture. Attached to the south side of the nave of the church is the ancient cloister, a square of about 120 feet, on the east side of which is the chapter-house, a decagon of 58 feet in diameter, and 45 in height, the roof of which is supported by a central column: it now serves as a library, as well as a council-room, and contains a valuable collection of books, and of manuscripts, chiefly relating to the canon law. Adjoining to the south side of the cloister is the ancient refectory of the monastery attached to the cathedral, called the college-hall, a lofty and spacious room, 120 feet long by 38 broad, now kept as the king's school. Here are also held the triennial musical meetings of the three choirs of Worcester, Hereford, and Gloucester, for the benefit of the widows and orphans of the clergy of their respective counties. This school was founded by Henry VIII. for forty scholars, who are prepared for the university, and instructed in various branches of modern education. A little to the eastward of the chapter-house stands the audit-hall, anciently called the Gueiten-hall, built in 1320, for the entertainment of strangers resorting to the monastery and cathedral. It is still the scene of hospitality during the annual audits of the chapter of the cathedral. At the back

WORCESTER.

of the seventh prebendal house, which formerly belonged to the kitchen or cook of the monastery, are the remains of the great kitchen, a spacious octagonal apartment, 34 feet in diameter.

Other places of worship belonging to the establishment in Worcester are, the churches of St. Peter the Great, St. Michael, St. Alban, St. Helen, St. Andrew, St. Clement, St. John Baptist, All Saints, St. Swithun, St. Martin, St. Nicholas, and Claines. Of these buildings, some preserve their ancient appearance. St. Andrew's church is distinguished by a square tower, 90 feet high, supporting an octagonal spire, in height 155 feet 6 inches; the whole height being 245 feet 6 inches. The church and tower are supposed to have been erected in the eleventh century, but the spire was not added till 1751. Among the various monastic institutions of Worcester was that remarkable one, now called the *Commandery*, established for the maintenance of two chaplains, five poor men, and two poor women, founded by St. Wulfstan, who died in 1097: it became, after the dissolution, a part of the endowment of Christchurch in Oxford. Commanderies were, among the knights-hospitaliers of Jerusalem, the same with the preceptories among the knights-templars; being societies placed on the country estates of the order, under the controul of a commander, but accountable to the grand prior or master in London. Part of the ancient buildings still exist; but the whole, now in the possession of a private individual, has of late years undergone great alteration.

Though containing so many parish-churches in proportion to the population, Worcester is not deficient in the number of chapels for various classes of dissenters. Among these, are reckoned Anabaptists, Independents, Methodists, Presbyterians, Quakers, and Roman Catholics.

On the south side of the cathedral and cloister is an open space, called the College-green, on the east side of which is a gate, known by the name of Edgar's tower, having on the outer front the statues of that king and his two queens, Elfreda and Elfrida. Antiquarian curiosity has been much excited by characters once existing on this tower, supposed to indicate a date much older than the received introduction of our present numerical figures into this part of the world. But the characters were probably misunderstood; nor is the tower itself believed to be of the age of Edgar, who died in 975.

Northward from the cathedral, on the rising bank of the Severn, is the bishop's palace, originally surrounded with embattled walls in 1270, but brought into its present state by bishop Stillingfleet and succeeding prelates. The west side still retains much of the antique architecture.

Public Buildings.—The chief of these is the guildhall, situated on the west side of the High-street, near the market-place. It is a handsome edifice of two spacious stories, finished in 1723: the lower part is in one room, 110 feet 6 inches long, by 25 feet 6 inches broad, and 21 feet high, in which are held the several courts of justice for the city and the county. The council-chamber is 109 feet long, by 26 broad, and 15 feet 8 inches high. The bridge over the Severn, in length between the abutments 270 feet, and in breadth 25, is an elegant stone structure of 5 semicircular arches, opened in 1781. The centre arch is in span 41 feet, but the other arches gradually diminish in width. Connected with the bridge a new street has been opened, leading into the middle of the city, and the new roads from the westward, the embankments, and quays along both sides of the river, are at once ornamental and useful.

Charitable Institutions.—The chief of these is the house of industry, completed in 1794, a handsome building on the east

side of the city, advantageously situated on an eminence, and calculated to accommodate 150 persons belonging to the different parishes of the city. The infirmary, situated in an airy position, overlooking the race-ground, the river, and the north-west parts of the county, was commenced in 1767: it receives about 58 patients on an average annually. A number of hospitals and alms-houses, some of ancient foundation, provide support for age, and education for youth. A free-school on the Lancafterian plan was established some years ago. The old county-gaol is situated in the castle-yard; but a new one has been lately erected in the neighbourhood of the infirmary, on the Howardian plan. The city-gaol is an ancient building in a crowded situation, having been originally a Franciscan convent, founded in the 13th century, but granted to the city at the dissolution.

Public Amusements.—Worcester has long maintained its claim to be one of the most fashionable cities in the western parts of the kingdom: it is consequently the winter-residence of a number of considerable families from the surrounding counties of England and Wales. The theatre, assemblies, concerts, races, the various public walks, clubs, the public library, &c. render Worcester a busy, gay, and much-frequented city.

Municipal Government.—The city was incorporated by Henry I., but the first charter was granted in the 45th year of Henry III. In 1621, the 19th year of James I., a mayor was established. The corporation now consists of a mayor, six aldermen, 24 common-council-men, and 48 assistants, by which last two bodies the magistrates are chosen. But the right of electing the members for parliament extends to upwards of 2000 citizens, the sheriff being the returning officer. Worcester sent two representatives to parliament in the 23d year of Edward I. Florence of Worcester, the author of the *Chronicon*, a general history of the world down to 1118, when he died, was a monk of the cathedral of this city. William of Worcester was educated in Oxford in 1434, and drew up his "Polyandria Oxoniensis," a history of the learned men bred in that university. His *Annals*, at the end of the "Black Book" of the exchequer, contain notes on the affairs of his own times. The famous empyric and mystic philosopher, Edward Kelly, was born in Worcester towards the middle of the 16th century. The relation of the impostures of this person and his associate Dr. Dee, furnished by Lilly, present a humiliating picture of the human mind and understanding in those days, on the continent as well as in England. Worcester produced, in 1650, the eminent lawyer lord Somers, who, by his knowledge and eloquence, defended the cause of liberty and justice in the latter part of the reign of Charles II., when but few warm and able advocates were found on their side in Westminster-hall. See SOMERS, Lord.

Worcester has long been rendered very interesting, from the circumstance of the *Royal Porcelain Works* being established within its walls. It is, on our part, a most pleasing duty, not only to trace its rise and progress, but to hold up its elegant and highly-finished productions to the attention of the liberal and scientific. A very material difference exists between this establishment, and others of a similar kind on the continent; as the improvements made by expensive experiments are here effected at the sole charge of the proprietors, while the most famed manufactories on the continent are supported and carried on at the cost of the government of the countries to which they belong. The Worcester porcelain works were founded in the year 1751, by Dr. Wall and a company of proprietors, composed of many gentlemen of fortune and consideration in the city and county; who continued to carry on the concern under those adverse circum-

stances generally attending the introduction of a *new species* of manufacture: for at that time little was known of porcelain in England, except by the imports from foreign nations. The Worcester porcelain company had the merit of discovering the method of transferring impressions from *engraved copper-plates* to the surface of the porcelain. The invention, after a lapse of several years, was conveyed into Staffordshire, and now forms a grand branch of the extensive foreign and home trade carried on in the potteries, giving employment to many thousands. The *founders* of this manufactory, besides the printing, produced neat enamelled designs, but not very superior either in design or execution. These extensive premises, situate on the banks of the Severn, were subsequently purchased by Messrs. Joseph Flight and Martin Barr, and by a liberal policy, and great exertion and expence in a long series of experiments, the productions of these works have risen rapidly in the public estimation. His present majesty, the queen, and princesses, in the year 1788, honoured the manufactory by minutely inspecting its various processes; and at this time the king graciously granted his patent, when these works were styled 'Royal,' being the first that enjoyed this distinction. His majesty condescended to suggest the establishment of a warehouse in London, and one was immediately opened in Coventry-street. The proprietors have since had the honour of receiving a patent and every encouragement from his royal highness the prince regent, the enlightened patron of the arts; and from the late princess Charlotte, as well as from other members of the royal family, and even from foreign courts; but our limits forbid our entering into detail. On the demise of Martin Barr, esq. in the year 1813, he was succeeded by his sons; and the works are now carried on under the firm of Flight, Barr, and Barr. It is not a little remarkable, that a considerable part of the export trade of the Worcester porcelain works is to our settlements in the East Indies, and even to Canton. We cannot but observe the singular change in our commercial relations in *this manufactory*; for the Chinese, who seventy years since furnished this country and nearly all Europe with porcelain, are now excluded from our markets, and thrown into the back-ground, and their extensive manufactories nearly ruined. What Wedgwood did in his coarser clays, in his beautiful imitations of the Etruscan vases, and in antique designs on jasper, will long live in the recollection of his country. The same spirit seems to actuate the proprietors of the Royal Worcester Porcelain Works, as they have spared no expence in *their finer materials*, and highly-finished models and paintings, to excel the manufactories on the continent. In these works, the utmost attention is paid to the study of historical compositions, landscapes, flowers, &c.; and the success which has attended the new method is most evident, as the productions now fairly rival the best foreign specimens. It is with peculiar pleasure we can at length announce, that we have seen a *fabric*, recently made by the present proprietors of these works, which in its colour, fracture, and transparency, is equal to the porcelain made at Sevre or Dresden. This fabric is composed *entirely of British materials*, and the fact must be the ground of triumph, after all that has been said of the impossibility of finding in this country proper materials for a *true porcelain*. The process is most curious and elaborate, of which we can but give a slight description, as its details are so numerous. It may be viewed by tickets, granted by order of the proprietors to any respectable individuals leaving their names. The materials, several of which are procured from the county of Cornwall, are first selected with great care, and some undergo a severe calcination previous to their being composed in proper proportions; they are then weighed and mixed,

and burnt in a kiln to a very intense degree of heat, and form what is termed a 'frit.' This is ground under a massive iron roller previous to an admixture of a certain proportion of the purest argil, or working clay, which is ground with the frit in a mill, the bottom of which is laid with stone, over which large stones of about fifteen hundred or a ton weight are driven by upright 'drivers,' fixed in wooden arms attached to the centre shafts; these, with water, reduce the substance to a thick white liquid, which is afterwards passed through an extremely fine lawn sieve, and is run from cisterns into large brick pans, warmed by flues underneath; the heat being sufficient to drive off, by evaporation, the water that cannot be collected on the surface, so that the residuum is a moist clay, which is afterwards tempered in stone vaults, and rendered fit for the use of the potter. The man who first brings the rude mass of clay into form, on a circular block, moved horizontally by a boy, who drives a vertical wheel, is called a 'thrower.' The dexterity and rapidity with which the clay appears to spring into the shape required seems like magic, as it is performed silently, and almost unperceived, by the pressure of the fingers and thumb. This mode of 'throwing' differs from the Chinese method, and that practised on the continent, where the thrower moves his block by the action of his feet: in the one he has the advantage of an undivided attention, and the clay is literally obedient to his touch; while in the foreign method, the thrower is distracted with two distinct operations, and at the best it can be but a clumsy exhibition. By this mode all *round vessels* derive their first formation; any article of an oval, square, or other shape, must be made off a mould formed of alabaster, prepared in a powder, and with water brought into a liquid form, when it is run on the model, and sets quite hard, presenting a case the precise reverse of the model, on which layers of clay, cut to a proper thickness, are pressed with a sponge and the hand, and the artist from this is termed 'a presser.' Great care is requisite in drying the different articles in a stove after they come from the thrower, to render them sufficiently firm to hang on a lathe, where they are reduced to a proper thickness, and a more accurate form, by a turner, who works his wheel on the same principle as one for wood or ivory. It is again committed to the stove, where it is rendered quite dry and crisp; and the surface is afterwards sponged, and then rubbed with paper perfectly smooth. In pieces which have any particular marks or decorations in the clay, they are pressed from moulds, and the handles are attached to the vessel simply by the clay reduced to a liquid form. When burnt, the union is so complete, that it appears to have been made altogether, and is perfectly as firm. We cannot trace the operations in this stage any farther, but are surprised to see how many hands the most simple article passes through, while the risk and labour in these and more elaborate specimens are very great in this tender state of the clay. From the potter's-stove the ware is carried to what is termed the biscuit-kiln, and placed in cases of fire-clay, called seggars, in which each piece requires particular supports to prevent its yielding to the fire, and losing its proper shape. Here the porcelain is burnt to an intense degree of heat, and is rendered quite white and transparent, but has a slight roughness on its surface. From hence it is carried to the warehouse, examined, freed from dust and other imperfections, and then dipped in a liquid termed the glaze, dried in a stove, and afterwards every piece is carefully examined and 'trimmed;' which consists in rendering the surface quite even, and scraping the glaze from the feet, which, if not removed, would *melt* and adhere to the cases in which they are burnt.

WORCESTERSHIRE.

From the glazing-room the articles are carried to the second kiln, and here they undergo another severe fire, which fluxes the glaze, and gives to the porcelain a beautiful glossy surface. In this kiln the losses are great, as the porcelain can have no support. It is again warehoused, examined, and delivered to the painters, who decorate it with gold, reduced by a chemical process, so that it may be worked in a liquid form. In paintings of various designs, the outline is made with a black-lead pencil, on the glazed surface, corrected with Indian ink; and the colours, all of which are prepared from mineral substances, worked in oil and spirits of turpentine, are laid on with fine camel's-hair pencils. The colours in this state are difficult for strangers to understand, as their tints are so surprisingly changed by the action of the fire; while their opaque and obscure appearance is increased at every stage of drying at a common fire, previous to their being burnt in the kiln. The finer kinds of paintings in figures, landscapes, flowers, &c. require repeated burnings, in order to give them sufficient depth and richness by working one tint over another. The enamelling kiln, in which they are fired, is rendered sufficiently hot to fuse the glaze, without occasioning it to run; while the colours, by the aid of their fluxes, are melted into the glaze, so as to render their union perfect, and give them their rich transparent effect.

The durability of these colours, which cannot be acted on by any atmosphere, renders good painting in this style very desirable. It has long been a desideratum with the greatest masters to procure colours for painting on canvas, on which time can have no injurious effect; but in this they have hitherto unfortunately not succeeded, and it was the regret of an eminent artist, that his paintings had not the permanency of porcelain colours. A method of printing, entirely different from the original mode invented by the founders of the works, is now carried on here. (For a description, see PRINTING on Porcelain, in the *Addenda*.) The last operation is the burnishing of the gold, which is executed with a stone, black in its external appearance, and remarkable for its hardness and the high polish it takes. This work is performed by women, who render the gold extremely brilliant by rubbing its surface with great care and skill. The embossed gold, for which this manufactory is celebrated, is burnished with a fineagate, which is also used in chasing and in finishing the handles of vases, &c. We have now sketched the process, but we should not omit to mention that in every stage the porcelain is very liable to accident and imperfections; and if not totally spoiled, it may require a repetition of firings, which much increases the risk and expence. The most costly articles are exposed in the fire from 150 to 200 hours, in their different stages collectively. An important colour used in porcelain manufactories is the rich dark blue, generally called 'royal.' It is prepared from cobalt, and the oxyd of this ore is so powerful as to require the heat of the glaze-kiln to bring out its beautiful tint. It is not, like other colours, worked on a glazed surface, but laid on the porcelain after the first burning, when in the rough or 'biscuit' state, then fired, and afterwards dipped in the glaze, and passed through the glaze-kiln, frequently requiring two or three such ordeals of heat to perfect its colour. We were formerly supplied with this mineral from the mines of Saxony, but have now the pleasure to learn that the proprietors of these works made some successful experiments for a company of gentlemen, who discovered cobalt-ore in Cornwall; which by a particular preparation produces as fine a blue as the Saxon cobalt, and it is now used in preference to the foreign, which can only be imported in the adulterated form of a zaffer. The reflection, that by science and labour

the rude materials of the earth are raised and converted into elegant and useful forms, and embellished with classical and tasteful designs, is highly pleasing; while it affords the means of maintenance to so many industrious workmen and ingenious artists. All the persons employed in these interesting works are British, and this manufacture stands as one proof of the increased civilization of England.—The History and Antiquities of Worcester; by Valentine Green, 2 vols. 4to. 1796. Beauties of England and Wales, Worcestershire; by F. C. Laird, 8vo. 1813. Graphic and Historical Description of the Cathedrals of Great Britain, Worcester, 8vo. 1815. History, &c. of Worcester, by J. Chambers, 8vo. 1818.

WORCESTER, the south-easterly county of the state of Maryland, with 16,971 inhabitants, including 4427 slaves.—Snowhill is the chief town.—Also, a county of Massachusetts, large and populous, with 50 townships, 53 congregational churches, and 64,910 inhabitants; 53 miles long from N. to S. and 40 broad.—Also, a town of the state of Massachusetts, containing 2577 inhabitants. This is the chief town of a county of the same name, and one of the largest inland towns in the state. It contains two churches, a town-house, and a gaol; 34 miles W. of Boston. N. lat. 42° 10'. W. long. 71° 46'.—Also, a township of Vermont, in the county of Chittenden, with 41 inhabitants; 30 miles N. of New Haven.—Also, a township of Pennsylvania, in the county of Montgomery, with 868 inhabitants; 18 miles N.W. of Philadelphia.—Also, a town of Ohio, in the county of Washington, with 385 inhabitants.

WORCESTERSHIRE, an inland county in the western part of England, bounded by Herefordshire, which separates it from Wales, on the S.W., by Shropshire on the N.W., by Staffordshire on the N., by Warwickshire on the E., and by Gloucestershire on the S. The form of the county is very irregular, having on every side detached parts surrounded by other counties, and comprehending within its bounds parts belonging to the neighbouring shires. The mean length may be estimated at about 30 miles, and the mean breadth at 25 miles, giving a surface of 750 square miles, or 480,000 acres; but according to the official report laid before parliament, the contents are reduced to 431,360 acres: about two-thirds of the county lie on the E. and one-third on the W. side of the river Severn. Worcestershire comprehends one city, eleven market-towns, three of them parliamentary boroughs, and in all 152 parishes; the whole is distributed into five hundreds. The inhabitants amounted, in 1811, to 160,546, of whom 78,033 were males, and 82,513 females, and the inhabited houses were 30,206.

Historical Events.—Worcestershire is supposed to have formed a part of the territory of the *Cornavii*, who also inhabited the contiguous districts of Warwickshire, Staffordshire, Shropshire, and Cheshire. That numerous tribe appear from the *Notitia Imperii* to have furnished bodies of troops to the Roman armies; but no trace of their name is now to be discovered in the tracts they are believed to have occupied. The county was called by the Saxons *Wirecestre-scire*, and in Domesday-book *Wirecestre-scire*, and the inhabitants in Bede's time were named *Wicci*; a term which, in the opinion of Camden, may have been derived from *Wicb*, signifying, in the old English language, a salt-pit, in allusion to the mines of that substance found in the county. Of the Roman history of Worcestershire but little is known. Ptolemy seems to take no notice of it; nor does it appear to be traversed by any of the roads traced out in the Itineraries of Antoninus. It is highly probable, however, that Worcestershire must have been the theatre of

parts of the exploits of Ostorius, when proprætor in Britain; because he was certainly posted on the *Sabrina*, now the Severn. The other river mentioned by the historians of his operations, the *Antona*, has been by some writers conjectured to be the Avon, which falls into the Severn in the S. part of the county, while others suppose it to signify the Nen of Northamptonshire. The Roman roads, of which vestiges are discovered in different parts of Worcestershire, although not known to be laid down in the Itineraries, sufficiently prove the county to have profited by the arts and the policy of the conquerors, in the opening of communications; one of the earliest and most effectual means of promoting civilization, as well as of establishing dominion, among a rude and vanquished people. One of these ancient or Roman roads is the Runced-way, or Ridge-way, on the E. side of the county, running between Worcester and Alcester, in Warwickshire: another is a paved way from Kenchester, in Herefordshire, pointing N.E. towards Worcester. The great Ikening-street enters the county from Staffordshire, and passes near Bromsgrove: another great road, supposed by Nash to be the ancient Portway, but now called the King's head-land, passes over Hagley common. According to Dr. Stukeley, a Roman road extended from Worcester down the bank of the Severn to Upton, and thence to Tewkesbury on the N. border of Gloucestershire, where it joined Ricning-streetway. Worcestershire formed a part of the Saxon kingdom of Myrcnaric, or Mercia-land, in Latin changed into Merka. This, by much the largest kingdom of that people in England, was founded by Crida about the year 586, and enlarged by Penda, under whom the Christian religion was introduced among the Merkiens. During the struggles between the native Britons and their invaders, this part of the country must have suffered severely; but at last the Britons, driven from the plains, retired behind the Severn into the mountainous tracts of Wales. The ravages of the Danes in the 9th and 10th centuries were not unknown in Worcestershire; and to that people tradition ascribes various sepulchral and military antiquities discovered in it.

During the heptarchy, the greater part of Worcestershire, Gloucestershire on the E. of the Severn, and a portion of Warwickshire, were inhabited by the *Wiccii*, and under the jurisdiction of the bishop of Worcester: but on the accession of William of Normandy, the episcopal government was superseded, and the civil power entrusted to the sheriffs of Worcester. The first of these was Urfo of Abithoth, as he is styled in Domesday-book, son of the lord of that place, in Normandy, and brother of Robert Le Despenser, ancestor of the present families of that name in England. Urfo is also styled *Vice-comes*, having received from the king the hereditary shrievalty, with the constablership of the castle of Worcester. He sat in the great councils held in London in the 15th, and in Westminster in the 18th years of William I. During the conspiracy of Roger, earl of Hereford, and Ralph, earl of Norfolk, he prevented the former from passing over the Severn to form a junction with the insurgents. His daughter and heiress, Emmeline, married Walter, the progenitor of Beauchamp, whose family afterwards became earls of Warwick. The first earl of Worcester was Walleran de Mellent, a relation of the royal family. He held also the paternal honours in Normandy; but siding with the barons against Henry I., his estates were laid waste, himself long held a prisoner, and even when enlarged not entrusted with the keeping of any of his own castles. Taking part with Stephen against the empress Maud, his city of Worcester was carried by assault, and reduced to ashes. Dying a prisoner in Normandy, his

son inherited the Norman but not the English honours. All this happened in the 12th century; and the title of earl of Worcester seems to have lain dormant until 1397, when it was conferred on Thomas Percy, son of Henry, lord Percy, by his first wife Mary, daughter of Henry Plantagenet, earl of Lancaster, and brother of Henry I. earl of Northumberland. This gallant earl of Worcester, accompanying the Black Prince to France, &c. distinguished himself under the command of John of Gaunt, duke of Lancaster. The title in 1420 was bestowed on Richard Beauchamp, of the house of Warwick, descended from the first Norman sheriff or earl. He served with great reputation in France; but dying in 1449 without male issue, the title was granted to John Tibetot or Tiptoft, baron of Powis. Under Henry VI. he was charged with the guard of the narrow seas, and appointed lord-deputy of Ireland; and by Edward IV. justice of North Wales, constable of the Tower of London, and treasurer of the exchequer. Soon after he became chancellor of the kingdom, still, however, retaining his command at sea. It was not in military and state affairs alone that this nobleman distinguished himself. Educated at Oxford in all the learning of those days, he afterwards visited Jerusalem for devotion; also Padua, Venice, and Rome, to consult the libraries and the learned societies of those places; and was the author of several works. On the temporary restoration of Henry VI. by Neville, earl of Warwick, the earl of Worcester was apprehended and beheaded at London in 1471. His son was afterwards replaced in the family honours and estates by Edward IV.; but dying without issue in 1485, the title was, by Henry VIII., conferred on Charles, natural son of Henry, duke of Somerset. His grandson, Henry, was created marquis of Worcester by Charles I.; and his grandson, Henry, was, in 1682, by Charles II. created duke of Beaufort, the title of marquis of Worcester being by courtesy attached to the eldest son of that family to the present time.

State of Property.—Prior to the Norman Conquest, great part of the lands of Worcestershire belonged to the church; but on that event much was bestowed on the favourites and followers of the Conqueror. Very little is now possessed by the descendants of the ancient proprietors; for in the various revolutions of the kingdom, the adherents of the losing sovereign were in general deprived of their property. William Beauchamp, baron of Elmley, possessed great estates by descent from the first earl of Worcester; but lost them by adhering to the empress Maud against Stephen. They were restored however by Henry II. In the contests between king John and the barons, the grandson of William Beauchamp was a material sufferer; for having taken the side of the nobles, the church of Worcester, on the re-establishment of John's power, laid hold of the opportunity to enlarge their precincts, abridging the accommodations of the castle, so that it was no longer fit for the habitation of the sheriff and his retinue; and from that time it began to fall into decay. The whole county was then the property of, or possessed by ecclesiastics, and by a few barons; nor was it until a much later period that a more general division of lands, from various causes, took place. In the reign of Richard II., the Beauchamps, earls of Warwick, were again deprived of their lands: under Henry VII. other large possessors of land, who had borne arms in Bosworth-field, were stripped of their property. But the greatest forfeiture of lands in Worcestershire took place in consequence of the attainder and execution of Edward, earl of Warwick, who had taken the part of Perkin Warbeck against Henry VII. Considerable changes were also occasioned by the transfer under Henry VIII. of the

WORCESTERSHIRE.

the lands of the dissolved religious establishments, to his favourites and the nobles who co-operated in his schemes. In the unhappy reign and life of Charles I., Worcestershire was often the theatre of warfare; many estates were dilapidated or ruined, and but few really acquired; for the prices set on the church-lands by the parliamentary surveyors were so enormous, that though sold at nominally a few years value, the purchasers generally lost by the acquisition. In later times, the changes of property in this county have been numerous and frequent; but the causes of those changes depending on private motives and not on public interests, as in former days, they do not come within the scope of this article. It is, however, worthy of remark, that out of the great number of families who recorded their armorial bearings, on the first visitation of the county by the Clarencieux, king at arms, in 1533, only six or seven now remain, and of these only two reside on the ancient family estates. Of those named in the last visitation (1683) but few descendants now exist. By these changes, however, it has happened in Worcestershire, as in other districts where manufactures and commercial enterprise prevail, that the landed property is now distributed amongst a much greater number of proprietors, and that the country is incomparably better peopled and cultivated than in former times.

General Aspect, Soil, and Climate.—When viewed from any of the numerous surrounding eminences, Worcestershire assumes the aspect of a plain, the gentle slopes and risings on the east and west of the capital being then scarcely discernible. From those eminences also the cultivation of the plains is viewed to great advantage, as there are no tracts of considerable extent so barren or so neglected as not to present an agreeable as well as profitable verdure. On a nearer view, from a hill in the centre of the county, to the eastward of the capital, a most beautiful landscape presents itself; the whole back-ground, distant from eight to twelve miles, appears to be the continuation of one range of hills, enclosing rich and beautiful plains, in which the flourishing hop-grounds and plentiful orchards constitute very interesting and gratifying objects.

The soil of the county is various; but it chiefly consists of rich loamy sand, mixed with a small proportion of gravel, in the central parts on the north of Worcester. Towards the east the soil is a very light sand, containing a few spots of clay, and some peat-earth; but the eastern district of the county is, in general, a strong clay, the waste lands being principally a deep black peat-earth. Between Worcester and the vale of Evesham, in the south-east part of the county, the soil is partly red marl, and partly strong clay, whilst the subsoil in some places is composed of lime-stone. In the celebrated vale of Evesham, watered by the river Avon, the soil is particularly deep, of a darkish earth, resting on clay, and in parts on gravel. Farther south limestone prevails, in the upper lands, on the skirts of the Cotswold hills, and a rich loam in the lower lands. In the south-west division of the county, between the Severn and the Malvern hills, the soil is in general clay, mixed with sand or gravel; but farther to the northward the gravel increases, until it terminates in the light sands of the northern border of the county. In all of these districts, however, some rocky and stony soil is found; but according to Mr. Pomeroy, in his Agricultural Survey, no traces of chalk or flint anywhere occur; nor have any been found, it is said, in the lime-quarries. The vale of Severn is described by Mr. Pitt, in his subsequent survey of the county, to contain probably ten thousand acres of a deep rich sediment, deposited in the course of ages by the river and its tributary streams. In some parts, this sediment consists of a pure

water-clay, fit for brick-making, but generally of a rich mud, fertile and favourable to vegetation. The county has been lately distributed in the following manner:

	Acres.
Common fields of arable land estimated at	20,000
Inclosed ditto - - - - -	340,000
Permanent grass-land - - - - -	100,000
Kitchen-gardens, &c. - - - - -	5,000
Woods, wastes, rivers, roads, &c. - - - - -	35,000
Whole county about - - - - -	500,000

Respecting the corn-produce of the county, it is thus estimated in Pitt's survey: In 360,000 acres of arable land, 43,500 are supposed to be laid down in wheat, yielding from 20 to 32 bushels *per* acre, or 1,200,000 bushels on an average. From this quantity deducting 108,750 bushels, at $2\frac{1}{2}$ *per* acre, the remaining neat produce is 1,091,250 bushels.

The climate of Worcestershire, particularly in the middle, southern, and western parts, is stated to be remarkably mild, soft, and healthy. The vale of the Severn rises but little above the sea, and the valleys of the Avon and Teme are nearly on the same level; and the adjoining uplands, seldom rising at the most 150 feet higher, possess a warmth and softness which ripen the grain and bring to perfection the fruits of the earth, from a fortnight to a month earlier than in more elevated counties, even enjoying a similar soil and surface. The principal bleak and inclement parts are the Bredon and Broadway hills on the south border of the county, and the Lickey range on the north: for the Malvern hills on the west, although only sheep-pasture, possess a most salubrious climate.

Hills.—The highest hills are certain points of the Lickey range, which, rising to the north-east of Bromsgrove, runs north towards Hagley, and diverges to the eastward. Some of those points are estimated to be elevated 800 or 900 feet above the general level of the country. On this range is a small spring producing two streams, one of which flows northward to the Rea, which falls into the Trent, and with it is discharged into the German ocean on the east side of the island; the other, falling into the Stour, is carried by the Severn into the Bristol Channel on the west. Bredon-hill, in the south-east corner of the county, is of about equal elevation. The highest point of the Malvern range of hills, called the Herefordshire beacon, rises, according to the great ordnance survey of England, 1444 feet above the level of the sea: the Worcestershire beacon, barometrically measured, rises 1298 feet; and North-hill 1211 feet above the Severn.

Rivers.—These are, the Severn, the Avon, the Teme, and the Stour; the smaller streams are, the Salwarp, Arrowe, Ledden, Rea, &c. The Severn, called by the Romans *Sabrina*, is supposed to be so named from the British terms *sabr*, sand, or *sabrin*, sandy, because it is often turbid, especially when heavy rains fall on the Welsh mountains. See SEVERN.

The river Avon is said to have been originally so named by the Britons, on account of the gentleness of its course. It is commonly distinguished from a number of other rivers in Britain of the same name, as the Warwickshire-Avon, and will be ever memorable while the name of Shakspeare remains. Entering Warwickshire towards the south-east corner, the Avon, by a winding course, waters the vale of Evesham, passes by Pershore, and unites with the Severn in the neighbourhood of Tewkesbury. It is navigable for barges

barges through the whole extent of the county, by means of locks in different places. See AVON.

The Teme, rising in Radnorshire, enters Worcestershire a little above Tenbury, and thence pursuing a winding but rapid course, through a succession of beautiful and romantic scenery, along the woods and dales of Stanford, the seat of sir Edward Winnington, bart., it is lost in the Severn below Worcester. From the declivity of its bed, and consequent rapidity, it is navigable for barges only up to Powick bridge, a mile and a half from the Severn. But although on this account the Teme be of little commercial use, it is peculiarly ornamental to the county, no part of which surpasses the banks of this stream in variety of ground, wood, and open lawn. A ramble along its various windings, extending upwards of twenty miles, through a succession of orchards, hop-grounds, corn and pasture land, is, in autumn, peculiarly agreeable. The Stour, an inconsiderable stream, has risen into notice since the opening along its course of the important canal by Kidderminster, uniting the Severn and the Mersey. The Salwarp pursues its short course to the Severn by Bromsgrove and Droitwich, where it formerly received the overflowings of the salt-springs, but these are now turned into the new canal from that town to the Severn. The other little streams of Worcestershire merit no particular notice.

Canals.—Connected with the natural rivers are the artificial canals opened throughout the county. These are, the Trent-and-Severn, or the Staffordshire and Worcestershire canal, more commonly called the Stourport canal, from the place where it falls into the Severn, eleven miles north from Worcester; the Droitwich canal, for the conveyance of the produce of the salt-springs to the Severn; the Worcester and Birmingham canal; the Dudley extension canal; and the Leominster canal, near Tenbury. See CANALS.

Woods and Forests.—About the time of the Norman Conquest, Worcestershire was considered to possess five forests; namely, those of Feckenham, Ombersley, Horewell, Malvern, and Wyre; but of the last only a small portion lies within the county. Feckenham forest, once very extensive, has now almost disappeared, owing to the continual demand for fuel to the salt-works at Droitwich, until of late years a sufficient supply of pit-coal has been obtained. Ombersley forest, on the north of Worcester, and Horewell forest on the south, have long been disafforested. Malvern forest or chase extended between the Severn and the summit of the hills of the same name, where may still be traced the trench which divided the forest and the county from Herefordshire on the west. Wyre forest, on the north border of the county, now more properly belongs to Shropshire and Staffordshire. Besides the vestiges of these forests, the county contains several tracts of woodland, of oak, elm, and beech: but from the demand for young trees to make hop-poles, and for trees to be converted into charcoal for the iron-works in the neighbouring counties, much timber of superior size cannot now well be expected in Worcestershire.

Mineralogy.—The minerals of this county are neither numerous nor peculiarly valuable. Clay and lime-stone are abundant; but coal, to render the latter useful in agriculture as well as building, is not easily procured where the stone is found. Some coal is indeed raised in the north-west district, about Mamble, where is a rail-way leading to the Leominster canal. Coal is also found at Penfax, and the Whitley-hills, in the same quarter, and is much used for coke for the hop-kilns and lime-pits; but the vein is too thin to promise much advantage to the county at large, which is principally supplied from the Staffordshire mines, by means of the Severn. In the vale of Evesham, and many other parts of the county, fuel is particularly

scarce and dear. The lime-stone quarries about Dudley are very extensive, and extremely curious excavations: but although the town stands in a detached part of the county, inclosed by Staffordshire, those quarries actually belong to the latter county. Building-stone of different sorts is also found in several parts. But the principal mineral riches of Worcestershire arise from the salt-mines of Droitwich, a parliamentary borough, situated six miles north-east from Worcester, on the road to Birmingham. These salt-works are of great antiquity, having been granted by Kenulph, king of Mercia, to the church of Worcester, in 816; and it appears from Domesday-book, that shares in them were annexed to many estates at even a considerable distance, on account probably of the wood they yielded for the manufacture of the salt. The principal brine-pits, however, belonged to the crown, but were granted by king John to the burgesses of Droitwich. The general substratum of the environs of the town is supposed to be a salt-rock, lying usually from 150 to 200 feet below the surface. On boring in any part, the salt-springs are met with about 110 feet below the surface: the boring-machine then passes through about 130 feet of gypsum to the brine-river, in depth about 22 inches, beyond which is a bed of salt-rock hitherto unexplored. In searching for this brine-river some years ago, the miners passed through four feet of mould, 32 of marle, 40 of gypsum, a brine-river of 22 inches, and 75 feet of another stratum of gypsum, below which they came to the salt-rock. (See DROITWICH and SALT.) For an account of the mineral waters of *Malvern*, see that article; and more particularly the paper of Mr. Horner, in the first volume of the Geological Society of London. Besides these, Worcestershire has some chalybeate springs at Sandbourne and the Round-hill, in the parish of Kidderminster.

Manufactures and Commerce.—The commerce of Worcestershire is considerable, from its own productions, and from the deposit and transit of those of the neighbouring mining and manufacturing districts. Of its own products may be noticed the hops, fruit, cyder, and perry, which render the capital the principal mart for those articles in the western part of the kingdom. The county also exports a considerable surplus of its own manufactures, consisting of Kidderminster stuffs and carpets; of Worcester gloves, china and glass-ware, and of nails, bar and sheet iron. Great quantities of salt are annually sent from Droitwich; Evesham furnishes oil and oil-cake; timber, grass-seeds, corn, flour, malt, salmon, cattle and sheep, and other agricultural productions are furnished by the county in general.

Civil and Ecclesiastical Divisions.—Worcestershire is divided into five hundreds; viz. Ofwaldeflow, Halfshire, Dodding-ton, Perfhore, and Blackenhurst: the first containing the capital and the centre of the county, with several detached portions in other quarters; the second occupying the north-west parts; the third, the north-east; the fourth, the south; and the fifth, the south-east quarter, around Evesham. In ecclesiastical matters, the county is under the government of the bishop of Worcester, and contains 152 parishes. The diocese was formerly of great extent; but in 1541 the see of Gloucester, and in 1542 that of Bristol, being erected, a considerable part of the episcopal jurisdiction of Worcester was withdrawn. At present the bishopric comprehends all the county, with the exception of 15 parishes and 8 chapelries belonging to Hereford; about one-third part of Warwickshire, together with the parishes of Brome and Clent in Staffordshire, and Hales-Owen in Shropshire. The diocese thus contains 116 rectories, 79 vicarages, 26 curacies, and 41 chapelries, all distributed into 9 deaneries.

Parliamentary History.—Worcestershire has been represented in parliament ever since the third year of Edward III., and at and ever since the revolution has maintained a respectable character for independence in the choice of its representatives. In the early part of the last century, sir John Pakynton accused the bishop of interfering in the election, of forbidding the clergy to vote for sir John, of threatening the tenantry of the see not to renew their leases if they voted for him, and even of desiring the baronet to withdraw his pretensions. The charges were established; and after a long contest between the two houses of parliament, on an address to queen Anne, the bishop was dismissed from his office of almoner. Worcestershire, which is included in the Oxford circuit, sends nine members to parliament; viz. two for the county, two for the city of Worcester, two for each of the boroughs of Droitwich and Evesham, and one for the borough of Bewdley.

Mansions and Country-seats.—Of these, Worcestershire contains a very considerable number, some of which are highly deserving of notice. Hagley-park, the “British Tempe” of Thomson, the favourite seat of the ingenious and amiable lord Lyttelton, the historian of Henry II., is situated toward the northern frontier of the county. The grounds have long been celebrated for variety and beauty of scenery. Croome-court, the handsome seat of the earl of Coventry, eight miles to the south of Worcester, is more indebted to modern art and skill for its beauties than to the natural features of the ground. The agricultural improvements, chiefly carried on by the late earl, are both extensive and important. Six miles north from Worcester is Omberley, the residence of the marchioness of Downshire, in the midst of spacious grounds. The house has been lately modernized. Grafton-hall, about a mile west from Bromsgrove, the property of the earl of Shrewsbury, was in ancient times a capital mansion; but being burned down in 1710, the porch and a part of the hall alone remain as specimens of its original magnificence. The latter has been converted into a chapel for a modern building annexed. Madresfield, six miles south-west from Worcester, the residence of viscount Beauchamp, is an ancient baronial castle, greatly altered in the modern style. Whitley-court, the seat of lord Foley, eight miles north-west from Worcester, is a highly improved and spacious mansion, in the midst of an extensive park. The parish-church, closely adjoining to the house, is one of the most elegant in the kingdom. Annexed to the see of Worcester is the ancient castle of Hartlebury, the residence of the bishops from the time of Henry III., situated between nine and ten miles north from Worcester. The principal part of the buildings, as they now stand, is the work of bishop Hough. Much of the improvements, however, are due to the late bishop Hurd, who furnished the palace with a valuable library, for the use of his successors in the see, in which are the principal books from the libraries of Mr. Pope and bishop Warburton.—Collections for the History of Worcestershire, by the Rev. Tredway Nash, D.D. 2 vols. fol. Lond. 1781-2. Supplement to ditto, ditto, 1799. General View of the Agriculture of the County of Worcester, by William Thomas Pomcroy, 4to. Lond. 1794. General View of the Agriculture of the County of Worcester, by W. Pitt, 8vo. Lond. 1813. Beauties of England and Wales, Worcestershire, by F. C. Laird, 8vo. Lond. 1816.

WORCUM, or **WoudricheM**, or *Wodercum*, a town of Holland, situated on the south side of the Wahal, first surrounded with walls in 1460, and defended with four bastions; 13 miles E.N.E. of Dort.

WORCUM, a sea-port town of Friesland, situated in a

fertile country, but subject to inundations of the sea, especially when the wind blows from the east. The harbour is blocked up with sand, but it carries on a considerable trade by means of its canals; 18 miles S.W. of Lewarden. N. lat. 53°. E. long. 5° 35'.

WORD, in *Language*, is an articulate sound, designed to represent some idea.

WORD, in *Writing*, is an assemblage of several letters, forming one or more syllables, and signifying some thing.

The Port-royalists define words to be distinct articulate sounds, agreed on by mankind for conveying their thoughts and sentiments.

The proper character of a word, according to the ingenious Mr. Harris, is that of its being a sound significant, of which no part is of itself significant; and hence he infers, that words are the smallest parts of speech.

The first and most obvious distinction of words is into such as are significant absolutely or by themselves, and such as are significant by relation: the former may be called principals, and the latter accessories. Moreover, all words whatever, significant as principals, are either *substantives* or *attributives*; and those, which are significant as accessories, acquire a signification either from being associated to *one word*, in which case they only define and determine, and may justly be called *definitives*, or to *many words at once*, in which case they serve to no other purpose than to connect, whence they are called *connectives*. Accordingly, Mr. Harris refers all words to these four species. Hermes, p. 20, &c. See **SPEECH**.

Grammarians divide words into eight classes, called *parts of speech*; which are, the *noun*, *pronoun*, *verb*, *participle*, *adverb*, *conjunction*, *preposition*, and *interjection*; to one or other of which, all the words and terms in all languages, which have been, or may be invented to express our ideas, are reducible. See each.

Words, again, are divided into *primitives* and *derivatives*, *negative* and *positive*, *simple* and *complex*, *common* and *proper*, *abstract* and *concrete*, *synonymous* and *equivocal*.

With regard to their syllables, words are farther divided into *monosyllables* and *polysyllables*.

The grammatical figures of words, which occasion changes in the form, &c. thereof, are, *syncope*, *apocope*, *apostrophe*, *diarexis*, *apharexis*, *prosthesis*, *epenthesis*, *paragoge*, *metathesis*, &c. See **SYNCOPE**, **APOCOPE**, &c. See also **FIGURE**.

The use of words, we have observed, is to serve as sensible signs of our ideas; and the ideas they stand for in the mind of the person that speaks, are their proper significations.

Simple and *primitive* words have no natural connection with the words they signify; whence there is no rationale to be given of them: it is by a mere arbitrary institution and agreement of men, that they come to signify any thing. Certain words have no natural propriety or aptitude to express certain thoughts, more than others: were that the case, there could have been but one language.

But in derivative and compound words the case is somewhat different. In the forming of these, we see a regard is to be had to agreement, relation, and analogy: thus most words that have the same ending, have one common and general way of denoting or signifying things; and those compounded with the same prepositions, have a similar manner of expressing and signifying similar ideas in all the learned languages where they occur.

For the perfection of language, it is not enough, Mr. Locke observes, that sounds can be made signs of ideas; unless these can be made use of, so as to comprehend several

particular things; for the multiplication of words would have perplexed their use, had every particular thing needed a distinct name to be signified by.

To remedy this inconvenience, language had a farther improvement in the use of general terms, by which one word was made to mark a multitude of particular existences; which advantageous use of sounds was obtained only by the difference of the ideas they were made signs of: those names becoming general, which are made to stand for general ideas; and those remaining particular, where the ideas they are used for are particular.

Some of our philosophers have complained much of the great use, or rather abuse, of vague and general terms, which have no precise definite signification. To distinguish these, F. Malebranche observes, that every thing that is, and consequently every thing that is intelligible, is either a being, or a mode and manner of being. Hence it is evident, that every term which does not signify either of these, signifies nothing, and is an obscure and confused term. In metaphysics, the use of such terms, he says, is sometimes necessary and allowable, as in speaking of the divine perfections, &c. But in physics it is always mischievous, however common.

It is observable, that the words which stand for actions, and notions quite removed from sense, are borrowed from sensible ideas; as, to imagine, apprehend, comprehend, understand, adhere, conceive, instil, disgust, disturbance, tranquillity, &c. which are all taken from the operations of things sensible, and applied to modes of thinking. *Spirit*, in its primary signification, is no more than breath; *angel*, a messenger. By which we may guess what kind of notions those were, and whence derived, which filled the minds of the first beginners of languages; and how nature, even in the naming of things, unawares, suggested to men the originals of all their knowledge: whilst, to give names that might make known to others any operations they felt in themselves, or any other ideas that came not under their senses, they were forced to borrow words from the ordinary and known ideas of sensation.

The ends of language, in our discourse with others, are chiefly three: first, to make our thoughts or ideas known one to another. This we fail in, 1. When we use names without clear and distinct ideas in our minds. 2. When we apply received names to ideas, to which the common use of that language doth not apply them. 3. When we apply them unsteadily, making them stand now for one, and anon for another idea.

Secondly, to make known our thoughts with as much ease and quickness as is possible. This men fail in, when they have complex ideas, without having distinct names for them; which may happen either through the defect of a language, which has none; or the fault of the man, who has not yet learned them.

Thirdly, to convey the knowledge of things. This cannot be done, but when our ideas agree to the reality of things. He that has names without ideas wants meaning in his words, and speaks only empty sounds. He that has complex ideas without names for them, wants dispatch in his expression. He that uses his words loosely and unsteadily, will either not be minded, or not understood. He that applies names to his ideas, different from the common use, wants propriety in his language, and speaks gibberish; and he that has ideas of substances, disagreeing with the real existence of things, so far wants the materials of true knowledge.

WORDS, *Division of*. See DIVISION.

WORDS, *General*. See GENERAL.

WORDS of Command. See EXERCISE.

WORD, *Watch-Word*, in an *Army* or *Garrison*, is some peculiar word or sentence, by which the soldiers are to know and distinguish one another in the night, &c. and by which spies and designing persons are discovered.

It is used also to prevent surprizes. The word is given out in an army every night by the general, to the lieutenant, or major-general of the day, who gives it to the major of the brigades, and they to the adjutants; who give it first to the field-officers, and afterwards to a serjeant of each company, who carry it to the subalterns.

In garrisons it is given, after the gate is shut, to the town-major, who gives it to the adjutants, and they to the serjeants.

WORD, in *Heraldry*, &c. See MOTTO.

WORDS, *Defamatory, Treasonable*, &c., in *Law*. See DEFAMATION, SCANDAL, and TREASON.

WORDEN, in *Geography*, a town of the duchy of Holstein, on the right side of the Elbe; 10 miles N.W. of Gluckstadt.

WORDEN, *Grossen*, a town of the duchy of Bremen; 10 miles N.N.W. of Stade.

WORDERNBERG, a mountain of the duchy of Stiria; 6 miles S.S.E. of Eisenhartz.

WORDINGBERG, a sea-port of Denmark, situated on the fourth coast of the island of Zealand, opposite the island of Falster. In the year 1066, Waldemar I. built a strong castle here, which is now gone to decay. Waldemar III., who was exceedingly fond of this place, resided here for the most part; and in derision of the Hanse towns, built the well-known tower, which, from a golden goose erected on the top of it, he called *Gans*, that is, *The Goose*. In this tower, he purposed to confine the prisoners of the Hanse towns that should fall into his hands in the war he intended to carry on against them. As the old castle gradually fell to decay, prince George, who was brother to Christian V., and married to Anne, queen of England, built here an entire new castle, which Frederick IV. afterwards enlarged; but that edifice has been pulled down. The usual passage to the islands Falster and Laaland is from this place. In 1240, at a famous diet held here, the Old Justische Low-buck, or Codex Legum Juricarum, was compiled and promulged: this body of laws is still in force in South Jutland. In 1256 another diet was held here; and in 1658, preliminaries for a peace between Denmark and Sweden were treated of in this town; 43 miles S.W. of Copenhagen. N. lat. 55° 3'. E. long. 11° 58'.

WORE. See WYRE.

WORENZUTTE, a town of Prussia, in Ermeland; 8 miles S. of Heilsberg.

WORGAN, Dr. JOHN, in *Biography*, a musical graduate of Oxford, organist of St. Mary-Axe, Bedford chapel, and many years a distinguished performer on the organ at Vauxhall, and Dr. Arne's successor there in the composition of cantatas, songs, and ballads.

He learned the rudiments of music of his elder brother, who had likewise an organist's place in the city, and played the violoncello in the Vauxhall band. Their scholars on the harpsichord were very numerous, particularly within Temple-bar; and John, as an organist and opener of new organs, rivalled Stanley. He was a very studious man, and dived very early into the old ecclesiastical composers of Italy. He succeeded Gladwin in playing the organ at Vauxhall. His first study in composition and organ-playing was directed by Roseingrave, who pointed his attention to the pure harmony and modulation of Palestrina, and organ-fugues of Handel. His constant use of the organ at Vauxhall, during the summer,

summer, ranked him with Stanley and Kceble; and his enthusiasm for Scarlatti's lessons, with which he was impressed by Roseingrave, rendered him equal to Kelway in their execution.

With an extempore prelude, *alla Palestrina*, and one of Handel's organ-fugues, he used to preface his concerto every night.

At length he got acquainted with Geminiani, swore by no other divinity, and on consulting him on the subject of composition, he was told that he would never be acquainted with all the arcanæ of the science, without reading "El Porque della Musica," a book written in Spanish per Andres Lorente, en Alcalá, 1672. But where was this book to be had? Geminiani told him, and told him truly, that the tract was very scarce. He had, indeed, a copy of it himself; but he would not part with it under twenty guineas. Worgan, on fire to be in possession of this oracular author, immediately purchased the book at the price mentioned; not understanding a word of Spanish, he went to work in learning it as eagerly as Rowe the poet, when lord Oxford had expressed a wish that he understood that language, which Rowe thought would qualify him for a good place under government. But after hard drudgery, when he hastened to acquaint the minister of state that he thought himself a tolerable master of the Spanish tongue, "I give you joy (says lord Oxford); you are now able to read Don Quixote in the original."

The knowledge of Spanish and study of Lorente seem to have had no other effect on Worgan's compositions, than to spoil his Vauxhall songs; which though sung into popularity by dint of repetition, had no attractive grace, or pleasing cast of melody.

He composed several oratorios, in which the chorusses are learned, and the accompaniments to his songs ingenious. The *cantilena* was original, it is true, but it was original awkwardness, and attempts at novelty without nature for his guide.

His organ-playing, though more in the style of Handel than of any other school, is indeed learned and masterly, in a way quite his own. In his youth, he was impressed with a reverence for Domenico Scarlatti by old Roseingrave's account of his wonderful performance on the harpsichord, as well as by his lessons; and afterwards he became a great collector of his pieces, some of which he had been honoured with from Madrid by the author himself. He was the editor of twelve at one time, and six at another, that are admirable, though few have now perseverance sufficient to vanquish their peculiar difficulties of execution. He is still in possession of many more, which he has always locked up as Sybil's leaves.

He had the misfortune to labour under two dreadful calamities; a bad wife, and the stone. He got rid of the former, after great mortifications and expence, by divorce; but in too early wishing to abridge his sufferings from the latter, he lost his life in the torture of an operation, August 20, 1790.

WORGÄUM, in *Geography*, a town of Hindoostan, in the country of the Mahrattas; 20 miles W. of Poonah.

WORK, in the *Manege*. To work a horse, is to exercise him at pace, trot, or gallop, and ride him at the manege.

To work a horse upon volts, or head and haunches in or between two heels, is to passage him, or make him go sideways upon parallel lines.

To **WORK**, in *Sea Language*, is to direct the movements of a ship, by adapting the sails to the force and direction of the wind. A ship is also said to work when she strains and

labours heavily in a tempestuous sea, so as to loosen her joints or timbers. See **ROLLING**.

WORK, *Carpenter's, Clock, Crown, Field, Fire, Fret, Grotesque, Horn, Mosaic, Out, Regimen of the, Rustic, Scratch, Stream, Vermicular, and Wax*. See the several articles.

WORK, *Discharge*, in *Calico-Printing, &c.* a peculiar kind of process, in which the cloth is first dyed of some uniform colour, by means of a mixture of iron-liquor and some one or more of the common vegetable dyeing substances; and calicoes thus prepared are said to be dyed of self-colours. They are then washed and dried, and when properly pressed or calendered, they are fit for receiving any pattern, according to the views of the artist. This operation is generally effected by means of the mineral acids, previously fitted for the purpose by dissolving in them a portion of one or more of the metals, according to the nature of the dye which is intended to be *discharged*, or of the colour to be produced. In doing this, the discharging liquor should be so made as to be capable of dissolving the iron which is contained in the dye, and which is always used in quantity sufficient for covering, or at least disguising in a great measure, the other colour or colours which had been employed with it, and at the same time for acting as a mordant in beautifying and fixing those colours. Thus a piece treated with a decoction of Brazil-wood, and dyed black by being *padding* with iron-liquor, if when dried it be printed with a peculiar solution of tin, the ferruginous portion of the dye will be dissolved, and the printed part will be instantly converted from a deep black to a brilliant crimson. The term *padding* denotes the operation of passing the pieces from a roller through a trough containing a solution of iron, or any other mordant, and is synonymous with *blotching*. In the same way, an olive-coloured calico, dyed in a solution of iron and a decoction of weld, will be as speedily changed to a bright pale yellow; and the various drabs and flates of every shade which have been in their composition, will undergo as sudden a change by the same treatment; though the colour of the figures produced upon them will depend on the materials with which the cloths were originally dyed. Even the deepest gold colours, or strongest buffs, if produced by iron only, may, by a peculiar preparation of tin, be discharged; and those parts of the cloth which have been treated with this metallic solution, will be restored to their former whiteness. Calicoes also, dyed of a light blue in the indigo-vat, then passed through sumach and copperas, and finished in a bath of quercitron bark and alum, may have figures of a bright green imparted to them. In this case, the green is originally formed by means of the indigo-vat and the bark, though it is enveloped by the iron of the copperas, which overcomes the other colours, till the solution of the tin is applied, which removes the iron from those particular parts, and gives a brilliancy to the remaining colour, which they would not otherwise have possessed; the tin being a powerful mordant for the bark, by which the yellow of the green is procured. A good self-colour may likewise be given to calicoes, merely by dyeing them in sumach and copperas, and then running them through an alkaline solution of annotto; and here the figures produced by the application of a colourless solution of tin will be of a bright orange.

In the instances above cited from Mr. Parkes's *Essays*, vol. ii., he refers only to that branch of discharge-work in which all the purposes are attained by dissolving the iron that makes a part of the colour intended to be discharged; whereas the finer and more expensive work is done by a different process. The particular kind of chemical discharge-

work above-described is subject to the imperfection of not being perfectly fast; that is, the goods thus produced will not bear frequent washing like those which are done by the bath of madder or bark. In this connection with permanent colours, Mr. Parkes is led to mention a very valuable *green*, not long ago invented by a Mr. Iset of London, secured to him by patent, which was produced by printing ground indigo, mixed with a peculiar kind of solution of tin, and then fastening the indigo within the fibres of the calico, by means of that process denominated *china-blue dipping*. (See *DIPPING*.) After this, the goods are to be dyed in a copper of bark or weld, which converts the blue into a green, and the whites are to be cleaned by croft-bleaching, &c.

In another kind of discharge-work, the agent that is employed is the citric acid, in various degrees of concentration, according to the purpose to which it is to be applied, or the strength of the ground intended to be discharged. This is employed chiefly for the production of white figures upon self-coloured grounds produced by madder and sundry other dyes. The acid for this purpose is mixed with either gum or paste to a proper consistency for the black, the plate, or the cylinder, and from thence it is transferred to the piece; and wherever it attacks, the mordant, whether iron or alumine, is discharged, and a delicate white appears in its stead. In using citric acid for this purpose, a portion of one of the mineral acids is sometimes mixed with it. There is another species of discharge, on which the agent employed by the printers is the nitrous, and sometimes the nitro-muriatic acid. See *DISCHARGING of Colour* and *COLOUR*.

WORKALLEN, in *Geography*, a town of Prussia, in Oberland; 4 miles S.W. of Liebstadt.

WORK-HOUSE, a place where indigent, vagrant, and idle people are set to work, and maintained with clothing, diet, &c. See *HOUSE of Correction*.

Such are the Bridewells, and several other places about the city of London, or suburbs; such also was the foundation of that in Bishopsgate-street, for employing the poor children of the city and liberties, who have no settlement; and that for the parish of St. Margaret's, Westminster, called the Grey-coat hospital.

By 43 Eliz. cap. 2. the church-wardens and overseers, with the consent of two justices, are empowered to set to work the children of the poor and other destitute persons, and to provide for the relief of the lame, old, blind, and such as are poor, but not able to work; and they may erect, with the leave of the lord of the manor, on any waste or common, of which the parish is parcel, convenient houses of dwelling for the poor. (See *POOR*.) By 3 Car. IV. they may set up and use any trade, merely for the employment and relief of the poor. By 9 Geo. cap. 7. they may contract for the maintenance and employment of the poor in houses purchased or hired; and poor persons refusing to be lodged and maintained in such houses, shall be put out of the parish-books, and not entitled to receive relief from the church-wardens and overseers; and two or more parishes are allowed to unite in lodging their respective poor in one house; and the officers of one parish are allowed to contract with those of another for the maintenance, &c. of their poor. Moreover, by 8 & 9 Will. cap. 30. parish poor that are relieved are required to wear on the shoulder of the right sleeve of the uppermost garment, in red or blue cloth, a large Roman P, together with the first letter of the name of the parish or place to which they belong. By 24 Geo. II. cap. 43. no spirituous liquor shall be sold or used in any work-house, or house of entertainment for parish poor. The statute 22 Geo. III.

cap. 83. establishes many new regulations with regard to the maintenance of the poor; but leaves it optional in any parish or place whether they will adopt these, or retain the present mode. At Amsterdam they have a famous work-house, or house of correction, called the *Rasphuyse*, (which see,) which, by a privilege granted in 1602, has alone the right of shaving and cutting the dyer's woods, as brasil, fantal, campechy, saffaras, &c. Each person, tolerably strong, kept in the house, is obliged to furnish two hundred and fifty pounds of rasped wood *per day*; and the weaker, a certain proportionable quantity of chips.

WORKING to Windward, in *Sea Language*, denotes the operation by which a ship endeavours to make a progress against the wind. See *BEATING, PLYING, TACKING, and TURNING*.

WORKING Furnace. See *FURNACE*.

WORKING of Glafs. See *GLASS*.

WORKINGTON, in *Geography*, a considerable market and sea-port town in the ward of Allerdale-above-Derwent, county of Cumberland, England, is situated on the borders of the river Derwent, at the distance of 34 miles S.W. by W. from Carlisle, and 310 miles N.W. by N. from London. The manor was anciently possessed by the Culwens, now Curwens, a family of great consequence in the county, of whom eight out of ten, in successive descent, were knights of the shire. The present importance of the town has originated from the working of the collieries since the reign of queen Elizabeth, at which period the entire maritime strength of the county consisted of only twelve vessels, though the number now belonging to this port alone is more than 160, and many of them are from one to three hundred tons burthen. These are principally engaged in the exportation of coals to Ireland, and some few to the Baltic. The river is navigable to the town for ships of four hundred tons; and on each bank, near the mouth, are piers. The harbour is one of the safest on the coast; and many improvements have been recently made in the situation and construction of the quays. The appearance of the town is diversified: several of the ancient streets are narrow and irregular; those of modern erection are better formed; the public buildings are all of late date. The houses are principally disposed in two clusters: in that called the Upper Town a new square has been erected, in the area of which is the corn-market; at a little distance are the butchers' shambles. The church, a neat edifice, contains the monument of sir Patrick Curwen, baronet, who died in 1661. In the town are meeting-houses for Presbyterians and Methodists, and a Catholic chapel; also a theatre and an assembly-room. Two large weekly markets are held on Wednesdays and Saturdays for meat and other provisions. Corn is sold only on the Wednesdays, which is the principal market-day. Here are also two annual fairs for cattle, but of no great note. The principal manufactures are those of sail-cloth and cordage, and every thing connected with shipping. Vessels of from four to five hundred tons, copper-bottomed, are built here, and sold to the merchants of Liverpool, Cork, &c. In the population return of the year 1811, the town of Workington is stated to contain 1059 houses, and 5807 inhabitants. The parish includes the townships of Great Clifton, Little Clifton, Stainburn, and Winscales, making an addition of 726 to the population, and of 161 to the number of houses.

On an eminence, near the east end of the town, overlooking the river Derwent, is Workington-hall, the seat of John Christian Curwen, esq., who has nearly rebuilt it, from the designs of Mr. Carr of York, and greatly extended and improved the park and pleasure-grounds. The old mansion,

manſion, of which there are ſcarcely any remains, was caſtelled, purſuant to a licence granted by Richard II. to ſir Gilbert de Culwen in 1379. Mr. Gough obſerves, that the walls were ſo remarkably thick, that in making ſome recent improvements, a paſſage was excavated through one of them lengthways, leaving ſufficient thickneſs on each ſide to anſwer every purpoſe of ſtrength. In this manſion, Mary, queen of Scots, when ſhe landed in England in 1568, was hoſpitably entertained by ſir Henry Curwen, till he was required by queen Elizabeth to reſign his royal gueſt, who was removed to Cocker-mouth caſtle, and afterwards to that of Carlisle.—*Beauties of England and Wales*, vol. ii. Cumberland, by J. Britton and E. W. Brayley, 1802. *Lyfons's Magna Britannia*, vol. iv. 4to. Cumberland, 1816.

WORKS, OPERA, in *Fortification*, the ſeveral lines, trenches, ditches, &c. made round a place, an army, or the like, to fortify and defend it. See **LINE, PARALLEL, and TRENCH**.

The principal works in a fortrefs, or fortified place, ſee under **FORTIFIED Place, FORTIFICATION, &c.**

WORKS, Covenant of, in *Theology*. See **COVENANT**.

WORKSBORN, in *Geography*, a river of Northumberland, which runs into the North Tine.

WORKSOP, a market-town in the hundred of Baſſetlaw, and county of Nottingham, England, is ſituated 22 miles N. from Nottingham, the ſame diſtance N.W. from Newark, and 146 N. by W. from London. The town is ſmall, but neat and pleaſantly ſeated in a valley, near the ſource of the river Ryton. According to the population returns of 1811, the houſes were then 759; and the inhabitants 3702. A market, noted for malt, is held on Wedneſday, and fairs on the 20th of March, 20th of May, 21ſt of June, and 3d of October. Worksop, anciently Wirkenſop, was, before the Norman Conqueſt, the property of a Saxon nobleman. Long afterwards it belonged ſucceſſively to the families of Furnival, Nevill, and Talbot, earls of Shrewsbury. The Talbot eſtates deſcending to co-heireſſes, a part was conveyed to the Howards, earls of Arundel, afterwards dukes of Norfolk, by whom the lands of Worksop are ſtill poſſeſſed, and who, on this account, enjoy the privileges of furniſhing a glove for the king's right-hand at his coronation, and of ſupporting that hand while he holds the ſceptre. Worksop was in former times defended by a caſtle, long ago deſtroyed: but its ſcite is ſtill pointed out on a circular hill, encompassed with a trench, at the W. ſide of the town.

Worksop was formerly noted for its manſtery, founded by William de Lovetot, in the reign of Henry I., for canons regular of the order of St. Auguſtine. The inſtitution was ſubſequenty enriched by the gifts of various proprietors of the town; but at the general diſſolution its poſſeſſions were ſeized by Henry VIII. Few veſtiges of the manſtery now remain; but the church ſtill partly ſubſiſts, and is a noble ſpecimen of ancient architecture. What now remains is but the W. end of the original church, with two lofty towers. The W. entrance conſiſts of an arch with zigzag ornaments, whiſt the towers have the windows in a gradation of different ſtyles of architecture. The interior of the church, in length about 135 feet, conſiſts of a nave and two aiſles; the roof is ſupported by eight pillars, alternately octangular and cylindrical: the ancient pulpit is ſtill preſerved. On the N. ſide of the church are fragments of walls; and foundations are diſcovered in the adjoining meadows: but the moſt curious veſtige of the ancient buildings is a ruinous chapel, at the S.E. corner of the church, now uſed as a place of burial, of which the windows,

ſtill well preſerved, furniſh examples of the lancet form. The gate of the manſtery is nearly entire, and retains a few of the ſtatues with which it was formerly furniſhed. The church and church-yard contain ſome monuments for eminent perſons of former times: one is the tomb of John, brother of Ralph Nevill, the firſt earl of Weſtmoreland, and treaſurer of England. The trade of Worksop, and its appendage Radford, has been much promoted by the Cheſterfield canal, which paſſes cloſe by the N. end of the town. The ſale of liquorice, formerly conſiderable, has been for ſome years at an end, none being now raiſed in the neighbourhood. On the S.W. of the town ſtands the noble manſion of the duke of Norfolk, ſtyled *Worksop-manor*, in the miſt of a park, eight miles in circuit, containing a great variety of ground, and much ancient timber of a fine growth, having once been a part of the great foreſt of Sherwood. The original manſion was erected by the renowned Talbot, the firſt earl of Shrewsbury, on a ſcale of extent and magnificence ſuited to his character and fortune: but in 1761 the whole was unfortunately burnt down; by which accident, the loſs ſuſtained was very great, not only in the furniture, but in the library, the paintings, and the antique ſtatues, part of the celebrated Arundelian collection. Soon after this miſfortune, the duke of Norfolk commenced a new manſion, on a plan of great magnificence, comprising a quadrangle incloſing two courts; but the execution of the ſcheme was interrupted by the unexpected death of the heir of the family. One ſide, however, which is the front, has been finiſhed, and is 318 feet in length, of great elegance and grandeur. In the centre is a portico of ſix Corinthian columns, on a ruſtic baſement. In the tympanum of the pediment is an emblematic representation of the high alliances of the houſe of Norfolk; and on the points are placed three ſtatues. The body of the building is crowned with an open baluſtrade. The interior contains many valuable paintings and portraits of anceſtors and connections of the family. The chapel is adapted to the Roman Catholic ſervice, to which the dukes of Norfolk have always, with the exception of the late duke, been ſteadily attached: it ſerves as a place of worſhip for a number of perſons of the ſame perſuaſion reſiding in the neighbourhood.

At no great diſtance to the S. of Worksop-manor is Welbeck abbey, the ſeat of the duke of Portland. This place belonged to Sweyn the Dane before the Conqueſt. A manſtery is ſuppoſed to have been founded in the reign of Stephen, by Thomas de Cukeneſy, for Premonſtratenſian canons, who were removed from Newhouſe in Leiceſterſhire. In the reign of Edward III., the manor of Cukeneſy was purchaſed by the biſhop of Ely, and beſtowed on the manſtery. At the diſſolution it was purchaſed by a perſon named Whalley, from whom it came to ſir Charles Cavendiſh, youngeſt ſon of ſir William, who married the celebrated counteſs of Shrewsbury. The ſon of ſir Charles, afterwards duke of Newcastle, was the author of a well-known treatiſe on horſemanship. His grand-daughter, marrying John Hollis, duke of Newcastle, left an only daughter and child, who by marriage conveyed the eſtates to the earl of Oxford; and their only child and daughter by marriage transferred Welbeck to the anceſtor of the preſent proprietor. The manſion is a large irregular ſtructure, erected at different periods, containing, particularly within, portions of the ancient monaſtic buildings. The greater part of what is now ſeen was conſtructed about 1604. The interior contains many ſpacious and elegant apartments, which are decorated with a number of portraits of perſons important in English hiſtory.

The grand riding-house and stables were erected by the noted duke in 1623 and 1625: having been long neglected they have been of late years restored, and are now among the most remarkable in the kingdom. Welbeck-park is about eight miles in circuit, and contains noble woods of venerable oaks, some of very great age and extraordinary size. One in particular, noticed in Evelyn's *Silva*, was in his time thirty-three feet round at the bottom, and is conceived to be 700 years old: it is now much decayed. But the most remarkable tree is "the duke's walking-stick," in height about 112 feet; the solid contents are estimated at 440 feet. Near the gate leading to Work-sop is a group of trees, called the "seven sisters," there having been formerly seven stems springing from one root, but one has lately been broken off. The late duke formed an extensive piece of water in the park, and raised a bridge of three spacious arches over it, but which fell down just as it was completed.

About two miles to the eastward of the parks of Work-sop and Welbeck is that of Clumber, a seat of the duke of Newcastle. The mansion is a magnificent stone structure of three fronts, one of which is ornamented with a light Ionic colonnade. The apartments are spacious, particularly the state dining-room, sixty feet in length, thirty-four in breadth, and thirty in height, which is fitted up with great magnificence. In the various rooms are several very valuable paintings. The arrangements for the domestic accommodation of the family are well worthy of notice. The park, now eleven miles in compass, was not long ago a wide tract of forest-land. It is in a manner wholly the creation of the late duke of Newcastle. It now contains about 4000 acres; but half a century ago the ground was little better than a black heath, interspersed with bogs and marshes, through which ran a small stream. The park comprehends, however, two woods of ancient oaks, from one of which the mansion takes its name.

Adjoining to Clumber-park, on the south, is that of Thoresby, the seat of earl Manvers. The old house was destroyed by fire in 1745, after which it was rebuilt by the proprietor, the last duke of Kingston, grandfather of the present possessor. The mansion, which is rather a comfortable residence than a magnificent seat, consists of brick, on a rustic stone basement, with an Ionic portico of four columns in the principal front. The great stair-case, single at the bottom, but divided into two at the first landing, opens into a dome supported by columns, on which rests a gallery, which communicates with the upper chambers. The apartments contain some valuable portraits and paintings. The park is about thirteen miles in circumference, and contains several pieces of water, of which one, near the house, assumes the appearance of an extensive river.—Thoroton's *History of Nottinghamshire*, by Throsby, 3 vols. 4to. London, 1790. *Beauties of England and Wales*, Nottinghamshire, by F. C. Laird, 8vo. London, 1812.

WORLD, *MUNDUS*, the assemblage of parts which compose the universe.

The *duration* of the world is a subject which has been greatly disputed. Plato, after Ocellus Lucanus, held it to be eternal, and to have flowed from God, as rays flow from the sun. Aristotle was much of the same mind: he asserts, that the world was not generated, so as to begin to be a world, which before was none; and, in effect, his whole eighth book of *Phys.* and first book de *Cælo*, are spent in proving the eternity of the world.

He lays down a pre-existing and eternal matter, as a principle; and thence argues the world eternal. His argument amounts to this; that it is impossible an eternal

agent, having an eternal passive subject, should continue long without action.

His opinion was long generally followed; as seeming to be the fittest to end the dispute among so many sects about the first cause.

Epicurus, however, though he makes matter eternal, yet shews the world to be but a new thing, and says it was formed out of a fortuitous concurrence of atoms. See *Lucretius*, lib. v.

Some of the modern philosophers refute the imaginary eternity of the world, by this argument: that, if it be *ab aeterno*, there must have been a generation of individuals, in a continual succession from all eternity; since no cause can be assigned why they should not be generated, *viz.* one from another. Therefore, to consider the origin of things, and the series of causes, we must go back in infinitum, *i. e.* there must have been an infinite number of men, and other individuals, already generated; which subverts the very notion of number. And if the cause which now generates have been produced by an infinite series of causes, how shall an infinite series be finite, to give room for new generations? See *God*.

Dr. Halley suggests a new method of finding the age of the world, from the degree of saltiness of the *ocean*; which see.

It is another popular topic of controversy, whether the world be finite, or infinite? See the arguments on both sides, under *UNIVERSE*.

It is likewise disputed, whether the plurality of worlds be possible? See *PLURALITY*.

Some hold the affirmative, from an opinion of the infinite power of the Deity; it being a setting bounds to omnipotence to say, that he created so many bodies at first, and that he could not create more.

The Cartesians maintain the negative, upon these principles: that it is a contradiction to say, there are several worlds existing at the same time, since this implies several universes of created beings, the world being the *totum*. That if there were several worlds, they must either be at a distance from one another, or contiguous; but neither can be said: for were they contiguous, they would only constitute one; and were they distant, there must be something between. But what can be between? If it be extended, it is corporeal; and, instead of separating the several worlds, it will connect them all into one.

The *existence* of an external world has been much controverted. The arguments on either side, see under *ABSTRACTION*, *BODY*, and *EXISTENCE*.

The world is sometimes divided into *upper* and *lower*: the *lower*, or *sublunary*, is the globe of our *earth* (which see); and the *upper* includes the heavens, and heavenly bodies.

WORLD, *Axis of the*. See *AXIS*.

WORLD, *Map of the*. See *MAP*.

WORLD, *Soul of the*. See *ANIMA Mundi*,

WORLD, *System of the*. See *SYSTEM*.

WORLITZ, in *Geography*, a town of Saxony, in the principality of Anhalt; 5 miles E. of Dessau.

WORM, a river of Norway, which flows from the lake Mioss into the Glom, or Glomen.

WORMDIT. See *WARMSTADT*.

WORMHOUT, a town of France, in the department of the North; 5 miles S. of Bergues.

WORMIA, in *Botany*, a genus of plants first established by Rottböll, was named by him in memory of the famous Danish physician and naturalist, Olaus Wormius, successor

WORMIA.

of Caspar Bartholin in the professorship of medicine at Copenhagen. He died rector of that university in 1654. His Latin writings, on the history and antiquities of Denmark and Norway, are valued for their accuracy. His son William published, in 1655, the *Museum Wormianum*, a handsome work in folio, the second book of which, according to Haller, consists entirely of botanical subjects. Olau Wormius herein describes and figures several rare plants, or monstrous varieties, with a detail of their anatomy. His letters, not published till 1751, are said to contain many things relating to Botany.—“Rottb. Nov. Act. Hafn. for 1783. v. 2. 522. t. 3.” Salisb. Parad. at p. 73. De Cand. Syft. v. 1. 433.—Clafs and order, *Polyandria Pentagynia*. Nat. Ord. *Magnolice*, Juss. *Dilleniaceæ*, De Candolle.

Gen. Ch. *Cal.* Perianth inferior, of five roundish, concave, very obtuse, coriaceous, permanent leaves. *Cor.* Petals five, roundish, concave, larger than the calyx, tapering at the base, deciduous. *Stam.* Filaments very numerous, crowded, short, equal; anthers terminal, linear, longer than the filaments, shorter than the petals, recurved, bursting by a double orifice at the summit. *Pist.* Germens five, or more, superior, distinct, ovate, compressed, crowded; styles terminal, tapering, recurved, longer than the germens; stigmas notched. *Peric.* Capsules as many as the germens, and of the same form, each of one cell and one valve, bursting at the inner edge, crowned with one of the permanent styles. *Seeds* several, from 8 to 12, roundish, “each with a pulpy tunic at the base.” *Salisb.*

Ess. Ch. Calyx inferior, of five coriaceous, permanent leaves. Petals five. Anthers with two terminal pores. Capsules five, compressed, distinct, many-seeded. Styles thread-shaped. Stigmas notched. A genus of trees or shrubs, with rather twining stems, and round smooth branches. *Leaves* alternate, stalked, simple, oval, coriaceous, with a single mid-rib, and many transverse parallel partial ribs. *Stipulas* large, oblong, pointed, deciduous; the young ones convoluted, forming a terminal point, as in the *Magnolia* tribe. *Flower-stalks* about the ends of the branches, opposite to the leaves, angular, either racemose or panicled; often unilateral. *Flowers* white or yellow. *Calyx* remaining coriaceous and dry, not becoming pulpy, in which, as well as the separate stigmas, and elongated styles, this genus differs abundantly from *Dillenia*. (See that article.) M. De Candolle notices the two terminal pores of the anthers in *W. alata*, which he thought might afford a character for dividing the genus, if the same were not found in all the species. We find this character in *W. dentata*, as well as in our new *W. sericea*, and therefore venture to make it a part of the generic distinction.

1. *W. madagascariensis*. Madagascar Wormia. De Cand. n. 1.—“Leaves oval, bluntly sinuated. Clusters panicled.”—Gathered by Commerfon in Madagascar. An elegant tree, with thick round branches. *Stipulas* solitary, large, long, leafy, externally villous, deciduous, each leaving an annular scar on the branch. *Leaves* oval or orbicular, smooth, with broad, obtuse, shallow, marginal notches. *Footstalks* long, channelled above, and marked with transverse wrinkles. *Flower-stalks* nearly opposite to the leaves, erect. *Partial-stalks* single-flowered, without bractæas. *Petals* undulated, thrice as long as the calyx. *Seeds* roundish. *De Candolle*.

2. *W. dentata*. Toothed Wormia. De Cand. n. 2. (*Dillenia dentata*; Thunb. Tr. of Linn. Soc. v. 1. 201. t. 20. Willd. Sp. Pl. v. 2. 1253, excluding Rottböll's synonym. Poir. in Lam. Dict. v. 7. 151.)—Leaves ovate, abrupt, coarsely and rather sharply toothed. Foot-

stalks simple, triangular, smooth. Flower-stalks triangular, from three to six-flowered.—Gathered by Thunberg in Ceylon. We received a specimen, precisely answering to the above plate, in 1786, from professor David Van Royen, marked *Dillenia indica*; *Reaumuria* of Koenig, by whom it was gathered; and *Ghodaparra* of the Cinghalese. This is a tree, with round branches. *Leaves* four inches long, of a broad, elliptic-ovate figure, very abrupt, coriaceous; paler beneath; entire at the base; wavy at the sides; most toothed at the end; transverse ribs very straight. Convoluted *stipula*, at the end of the branch, acute, two-edged, smooth. *Footstalks* linear, narrow, near two inches long, acutely triangular, not bordered, smooth. *Cluster* simple, on a long, smooth, angular stalk, not quite opposite to the uppermost leaf, in our specimen consisting of six flowers, whose partial stalks are about an inch long. Thunberg represents three flowers only, whose petals are obovate, about an inch in length.

3. *W. triquetra*. Triangular Wormia. “Rottb. Nov. Act. Hafn. v. 2. 532. t. 3.” De Cand. n. 3.—Leaves ovate, bluntish, bluntly and slightly sinuated. Footstalks simple, triangular. Flower-stalks triangular, racemose.—Native of Ceylon. *Van Royen*. Described by De Candolle from a dried specimen. “Branches round, brown, smooth, with an elevated ring round the origin of each leaf. *Footstalks* straight, two inches long. *Leaves* oval, or oblong; rather tapering at the base; obtuse, or somewhat pointed, at the end; either entire, or very bluntly and slightly waved; the ribs pinnate, (as in the rest,) having about eight or ten lateral ribs at each side. *Flower-stalks* simple, nearly opposite to the leaves. Two outer calyx-leaves rather the largest. *Petals* concave. *Stamens* very short. *Germens* triangular, crowded. *Styles* reflexed.” Such is De Candolle's description, but he doubts whether this be a distinct species from the last. We have seen neither specimen nor figure, but the plant having been received from professor Van Royen, like our specimen of the preceding, rather confirms the doubt than removes it.

4. *W. alata*. Wing-stalked Wormia. De Cand. n. 4. (*Dillenia alata*; Banks Ic. unpublished, communicated with specimens, in flower and fruit, to Linnæus.)—Leaves oval, entire. Footstalks smooth, winged.—Gathered by sir Joseph Banks, in New Holland, near Endeavour river. The branches are round, smooth, except the annular scars left by the stipulas. *Leaves* three or four inches long, and above half as broad, smooth, obtuse, with distant transverse ribs, and copious reticulated veins; their under surface rusty-coloured, but polished. *Footstalks* an inch or an inch and a half long, winged at each side with an entire leafy border, contracted at the apex, and quite smooth. *Flower-stalk* opposite to the upper leaf of the branch, solitary, racemose, triangular, smooth, shorter than the leaves, bearing two or three yellow flowers, larger than those of *W. dentata*. *Petals* undulated. *Anthers* long, linear, with two pores at the end, like *W. dentata*. *Styles* sometimes nine or ten, recurved. *Capsules* coriaceous, gaping, apparently real follicles, with a number of round seeds, inserted into the margins, destitute, as far as we can see, of any pulpy tunic.

5. *W. sericea*. Silky-stalked Wormia.—Leaves oval, bluntly ferrated. Footstalks depressed, silky, as well as the flower-stalks and calyx.—Native of the East Indies. A specimen in the herbarium of the younger Linnæus, which he supposed to be *Dillenia indica*, is marked “*Mallei Mangajokeri*, a tree with snow-white flowers.” We cannot refer this to any thing in professor De Candolle's work. It undoubtedly belongs to the genus before us. The

branches

branches are round, strongly scarred; when young, finely downy. Leaves crowded about the extremity of each branch, apparently deciduous, being found on young shoots only, shaped like the last, and nearly as large, but somewhat serrated, and, in a young state at least, finely downy; their transverse ribs much more copious, straight, and parallel, than in that. Footstalks half an inch long, stout, broad, and depressed, blunt-edged, not bordered, densely clothed with fine, white, silky, permanent down. Stalks simple, single-flowered, silky, about the length of the footstalks, each opposite to a leaf. Calyx-leaves obovate, concave, an inch long; smooth within; silky at the back. The petals we have not seen. Filaments short. Anthers long, compressed, two-edged, each opening by two terminal orifices. Germens crowded together. Styles five, recurved at the extremity. Stigmas small, abrupt.

We have at the end of the article DILLENIA, hazarded an opinion, that the *D. elliptica*, *integra*, and *retusa* of Thunberg, as well as his *dentata*, above-described, belong to this genus of *Wormia*, to which professor De Candolle seems, by a remark under *D. integra*, in his Syst. v. 1. 437, disposed to agree. Probably he thought it best, having examined no specimens, to leave these plants where he found them, but we cannot omit the following, on the authority of Thunberg's figure.

6. *W. retusa*. Abrupt *Wormia*. (*Dillenia retusa*; Thunb. Tr. of Linn. Soc. v. 1. 200. t. 19. De Cand. Syst. v. 1. 437. Willd. Sp. Pl. v. 2. 1253.)—Leaves obovate, abrupt, distantly toothed, smooth. Footstalks hairy at the base. Stalks single-flowered, smooth.—Native of woods in Ceylon. Thunberg. A tree, apparently nearly related to *W. dentata*, but the flowers are solitary, and rather smaller, each on a simple stalk, opposite to the uppermost leaf. Styles five, evidently those of a *Wormia*, not a *Dillenia*.

WORMING, in *Ship-Building*, windling a rope close along the cuntlines of larger ropes to strengthen them, and make a fair surface for the service. See Plate I. fig. 46. Rigging.

WORMING, in *Animals*, an operation which is sometimes performed on the young of the dog and some other kinds. Young puppies are thus cut, in some cases, under an ignorant supposition that it prevents their going mad; but in reality to cure them, as it generally does, of the disposition to gnaw every thing in their way. It consists in the removal of a small worm-like ligament, situated beneath the tongue; and the part being afterwards sore for some days, the animal is thus weaned of his mischievous habits. See *Diseases of Dogs*.

WORMIUS, OLAUS, in *Biography*, a Danish physician, descended from a family which fled from Arnheim, in Guelderland, to Denmark, from the persecution of the duke of Alva, was born at Aarhus, in Jutland, in 1588, and finished his education at the university of Marburg; afterwards availing himself of the lectures which he attended in the principal German academies, and in his tour through France, Italy, Switzerland, and Holland. He then returned to Denmark in 1610, and having in the following year taken the degree of doctor in medicine at Basle, he passed through the Netherlands to England, and in 1613 returned to his native country, where by successive preferments he became professor of medicine in 1624, in consequence of the resignation of Caspar Bartholin. Although he obtained in 1636 a canonicate in the chapter of Lund, he continued his professional practice, and was often consulted by Christian IV. and Christian V. His knowledge of antiquities, medicine, and anatomy, was profound;

and in 1628 he discovered bones in the human skull, called after his name "sex ossicula Wormiana in futura cranii lamdoidea." His collection of curiosities was, after his death, lodged in the royal museum. He was thrice married, and had 18 children. He died in 1654. His writings were very numerous; and the principal of them are enumerated in the General Biography, to which we refer.

WORMS, in the *Linnaean System of Nature*. See VERMES.

WORMS, in *Husbandry*, are very prejudicial to corn-fields, eating up the roots of the young corn, and destroying great quantities of the crop.

Sea-salt is the best of all things for destroying them. Sea-water is proper to sprinkle on the land where it can be had; where the salt-springs are, their water does as well; and where neither are at hand, a little common or bay salt melted in water does as well.

Soot will destroy them in some lands, but it is not to be depended upon, for it does not always succeed. Some farmers strew on their land a mixture of chalk and lime; and others trust wholly to their winter-fallowing to do it; if this is done in a wet season, when they come up to the surface of the ground, and some nails with sharp heads be driven into the bottom of the plough.

If they are troublesome in gardens, the refuse brine of salted meat will serve the purpose, or some walnut leaves, steeped in a cistern of water for a fortnight or three weeks, will give it such a bitterness that it will be certain poison to them.

A decoction of wood-ashes, sprinkled on the ground, will answer the same purpose; and any particular plant may be secured both from worms and snails by strewing a mixture of lime and ashes about its roots. It is a general caution among the farmers to sow their corn as shallow as they can, where the field is very subject to worms. Mortimer's Husbandry, p. 328.

In the roots of some sorts of garden crops, such as the carrot, onion, shallot, cauliflower, broccoli, and some others, worms and maggots are not unfrequently very injurious and hurtful, unless they be destroyed in sufficient time to prevent such effects. In the first, much advantage is supposed to have been gained by the full use of pigeon dung in preventing the worm.

And in this and the other sorts of garden crops it is found, that much benefit in removing such evils may be produced by a proper succession of cropping, as that of following strawberries which have been four or five years planted with onions, and artichokes that have stood the same length of time with carrots; as these sorts of vermin do not attack either the strawberry or the artichoke. In some cases, it is supposed that it may be safe to crop two or three times with onions or carrots on the same spot, but not oftener, as some appearances of the worm and maggot are generally displayed in the second or third year; but that from the ground being four or five years under strawberries or artichokes, plants on which those vermin cannot subsist, they soon perish, and the land where the rows stood has all the advantage of a new soil.

Soot when applied as a manure is said to be a good preventive of the maggot in onion crops; and that shallots, as requiring only a small spot, may be much improved in growth, and entirely preserved from the maggot, by the application of old hot-bed dung as manure, in the bottoms of the drills, well-mixed with soot; planting the shallots on this mixed manure, and covering them in to a proper depth. The soot in this case prevents the appearance of the maggot, and at the same time greatly improves the strength
of

WORMS.

of the shallot plants: it is a method which has never been found to fail in preventing worms and maggots in such crops.

Cauliflowers, broccoli, and the roots of other such plants, may be preserved from the effects of worms, by watering the drills of them well with soap-suds before planting them out, and afterwards occasionally: this not only, it is said, prevents the worm, but encourages the growth of the plants, and in some measure prepares the ground for other vegetables that are liable to the same sort of attacks.

The maggot is considered by some as peculiar to the onion and shallot, and that whenever the former becomes diseased, it is most liable to its attacks; and that as it could never be detected in the soil, it is highly probable that the ova or eggs of it are deposited in the root, and may be hatched in the greatest numbers when the plants are in a sickly state. It is not supposed, that the maggot ever passes from one onion to another; but that any remedy which is sufficiently powerful to destroy the insect must inevitably destroy the onion itself; that all that can be done is, therefore, to select proper soils and situations for the onion crops.

It is remarked, however, that the maggot which attacks the carrot is unquestionably to be found in the soil, and that it visibly enters from without.

It is concluded on the whole, that worms and insects of these kinds in general are driven from their retreats under ground, by pouring bitter or acrid water upon it, as such in which green walnuts have been steeped, or of which a ley has been made by dissolving potash. See several papers in the first volume of the "Memoirs of the Caledonian Horticultural Society."

WORMS, in Medicine. Three species of worms infest the human body; namely, the *ASCARIS*, *LUMBRICUS*, and the *Tania* or *TAPE-Worm*; which see respectively.

Worms were formerly supposed to be a common cause of a series of morbid symptoms, especially in children; but it is now well understood, that the disease ascribed to their influence is a marasmus depending upon other morbid conditions of the alimentary canal. The symptoms of this disease have been already detailed, under the head of *Diseases of INFANTS*, to which we refer.

Tin is often recommended as a good remedy against worms, particularly of the flat kind. Dr. Alston, in the *Med. Ess. Edinb.* vol. v. art. 7. directs an ounce and a half of the powder of pewter-metal to be mixed in half a Scotch mutchkin, or about half a pint English measure of treacle, for children; but to grown persons, he gives two ounces of the powder of pure tin, passed through the finest hair-sieve, and mixed with eight ounces of treacle. As to the administration of this medicine, the original receipt directs half of it to be taken the Friday before the change of the moon; the day after, half the remainder, and the rest on Sunday. On the Monday, a purge is to be taken. The doctor thinks there is probably nothing in the particularities of the day; but says, the medicine succeeds well in several species of worms.

The efficacy of fern-root against worms was known in the time of Dioscorides; and towards the beginning of this century, Messieurs Andry and Marchant published accounts of successful modes of exhibiting it in these cases. But it has been principally celebrated of late as a specific in the cure of the *tænia*, or tape-worm.

Dr. Priestley, considering how fatal nitrous air is to insects, and likewise its great antiseptic power, conceived that considerable use might be made of it in medicine, in the form of clysters; and he apprehends, that if nitrous air was

diluted with common air, or fixed air, the bowels might bear it better, and that it might still be destructive to worms of all kinds, and be of use to check or correct putrefaction in the intestinal canal, or other parts of the system. Priestley's *Obs. on Air*, vol. i. p. 227.

WORMS, in Animals, a troublesome sort of vermin often found in the intestines of the horse, and some other animals, causing disease. See *BOTTS*, *EARTH-Worms*, *ASCARIDES*, *TÆNIA*, and *TERETES*.

With respect to the cause of worms in horses, it is imagined, that, as in the human subject, some constitutions are more inclinable to breed worms than others. Gibson says, the most usual cause of worms is foul or high feeding, which occasion crudities and slimy indigested matter in the stomach and bowels, (especially in horses that have been pampered for sale,) forming a proper nidus for worms. This indeed may be the case, but the primary cause of worms is that which occasions these crudities, to wit, a want of energy in the functions of the stomach and bowels, as worms are never found in animals perfectly healthy in these respects.

According to Gibson, the signs of worms in horses are various, according to their different kinds. The botts that many horses are troubled with in the beginning of summer are always found sticking to the rectum, and are often thrust out with the dung, along with a yellowish-coloured matter, like melted sulphur. They are no way dangerous there, but they are apt to make a horse restless and uneasy, and rub his breech against the posts. The season of their coming is usually in the months of May and June, after which they are seldom to be seen, and rarely continue in any one horse above a fortnight or three weeks. Those that take possession of the membranous portion of the stomach are extremely dangerous in causing convulsions, and are seldom discovered by any previous signs before they bring a horse into violent agonies. See *BOTTS*.

But the teretes or earth-worms give little disturbance to a horse, and would hardly be discovered, unless they were seen now and then to come away with the dung. Frequently horses void one or two, and no more; and sometimes they will void pretty large quantities of the young brood, not much larger than the ascarides, only of a red colour, and not white, as the latter generally are. They are most usual in autumn, or the beginning of winter, though a horse may now and then void one or two of these at other times of the year.

However, the ascarides, or small needle-like worms, are very troublesome to horses, breed at all times of the year, and often when one brood is destroyed another succeeds. These are not at all dangerous, yet when a horse is pestered in this sort of way, though he will go through his business tolerably well, and sometimes feed heartily, yet he always looks lean and jaded; his hair stares as if he was sickly, and nothing that he eats makes him thrive. That he feels pain, too, is plain, for he often strikes his hind foot against his belly, which shews where his grievance lies, and is sometimes griped, but yet without the very violent symptoms that attend a colic or strangury. He never rolls or tumbles, but only shews uneasiness, and generally lays himself down quietly on his belly for a little while, and then gets up, and begins to feed; but the surest sign is, when a horse voids these worms with his dung.

In regard to the cure, if a horse be troubled with botts, Gibson says, he may be relieved without much expence or trouble, only by giving him a spoonful of favin, cut very small, once or twice every day, in oats or bran moistened; and if three or four cloves of chopped garlic be mixed

WORMS.

with the favin, it will do better, for garlic is of great service in these complaints. Horses that are troubled with bots ought to be purged with calomel and aloetic purges before the weather grows too hot; and if they be kept to a clean diet after this, it will be a great chance if ever they are troubled with them any more. As the bots generally happen about the grass season, those horses that are turned out to grass often get rid of them there, by the first fortnight's purging; and, therefore, those that have the convenience of a good pasture for their horses need not be very solicitous about giving them medicines.

And the earth-worms, which some writers call *teretes*, *rotundi*, or *lumbrici*, are also best conquered by calomel and occasional aloetic purges, for worms often come away in purging, when, till then, it has not been known that the horse was troubled with them; and it has been observed, after these have been voided, that the animal has thriven better, grown more lively, and shewn more alertness at his business. There can scarcely be a better plan of treatment than is supplied in the following *formule*, recommended by Mr. Denny in his useful work:—Take of calomel, one drachm; aniseeds, in powder, half an ounce; treacle, enough to make a ball. This is directed to be given in the evening; and the next morning the following:—Take of succotrine aloes, in powder, one ounce; ginger, in powder, two drachms; treacle, enough to make a ball: and the above bolus and purgative ball must be repeated, with an interval of nine days, until the horse has taken three doses. Then it is advised to give the following alterative powder, daily for about a month; this process does not require any change of diet, or involve any hazard from the effects of cold:—Take of Ethiops mineral, crude antimony, prepared, and aniseeds in powder, each half an ounce; mix them. The management of the horse during this course of worm medicines is that in common cases of physic; but some prefer giving Barbadoes aloes for the removal of worms, thinking it the more efficacious, because its operation is very rough: and Gibson thinks it may be given to hackneys, and other horses of small value; but he never found it more efficacious than the succotrine, at the same time that it exposes a horse more to gripes and other dangerous disorders, unless it be properly managed. The following he gives as a cheap well-corrected purge of this kind:—Take of Barbadoes aloes, one ounce; salt of tartar, two drachms; ginger, grated, a drachm and a half; oil of amber, a middling spoonful; syrup of buckthorn, sufficient to make a ball. The only objection to this is the quantity of aloes, which would be too considerable even if of a milder sort for some horses.

It may be observed, that the sort of worms called ascarides sometimes come away from a horse in great numbers, with the help of a purge, and some get quite clear of them with purges only; but this does not very often happen, for the horses that breed ascarides, above all others, are subject to slime and sourness in their intestines. In the human body, ascarides are thought to be bred in the rectum, near to the fundament; but in horses no other kind than bots usually adhere to that gut. On the contrary, these worms in them seem to be lodged about the beginning of the small intestines near the stomach, where they feed on the alimentary parts of the chyle. The bots in a horse are often seen sticking near the sphincter ani, and are continually dropping away with the dung; but the ascarides are seldom seen there, except when the animal has had a purge given him, or when he falls into a natural purging, which often happens from the irritation of the bowels, and then they come away in very great numbers, accompanied

with much slime and mucus. Bots seldom alter a horse's looks, but these not only make a horse grow lean, and look emaciated, but on opening his mouth one may perceive a more than ordinary languid whiteness, and a sickly smell, instead of that liveliness of colour that is always perceivable in the mouth of a sound and vigorous horse; so that, whatever be the primary cause, these worms seem in a great measure to proceed from a vitiated appetite and a weak digestion, which renders them the more difficult to be removed; for which purpose recourse must be first had to the foregoing remedies, and after them, such medicines as are proper to strengthen the stomach, promote digestion, and give tone to the solids.

The treatment advised by Gibson for these worms is chiefly the following:—Take of calomel, prepared, two drachms; diapente, half an ounce; make these into a ball, with a sufficient quantity of conserve of roses, and give it in the morning, keeping the horse from meat an hour or two before and after the dose; and the next morning administer a moderate aloetic purge, taking great care to keep the horse from wet, or from any thing that may expose him to take cold. The above calomel ball and the purge may be repeated in six or eight days, and again in six or eight days more. Or the following mercurial purge may be given, which will be less troublesome, though not less efficacious:—Take of crude quicksilver, two drachms; Venice turpentine, half an ounce. Rub the quicksilver with the turpentine in a mortar till no particle of the former appear; then add, oil of favin, thirty or forty drops; succotrine aloes, in powder, half an ounce; ginger, grated, one drachm; syrup of buckthorn, enough to make it up into a ball.

One of these mercurial purges may be given in the foregoing manner, *viz.* one in six or eight days, with all the same precautions: it will work mildly, and with little or no griping or sickness. And another mercurial purge, which is proper to destroy worms and to cleanse the first passages, is this:—Take of diagridium, calx of antimony, and calomel, of each two drachms; succotrine aloes, six drachms; ginger, grated, one drachm; oil of favin, cloves, or aniseeds, thirty or forty drops; syrup of buckthorn, enough to form the ball. To be given as the preceding.

When a horse has gone through a course of these mercurial purges, some advise the following drink to be given two or three times a-week, or till the horse begins to thrive and look healthy:—Take of rue, camomile flowers, horehound, of each a handful; galangals, bruised in a mortar, three drachms; liquorice-root, sliced, an ounce. Boil these in a quart or three pints of forge-water fifteen or sixteen minutes in a covered vessel, and keep it covered till cold; then strain it through a piece of coarse canvas, and give it in the morning upon an empty stomach.

Powdered tin has likewise been advised with the intention of destroying worms; and also most of the preparations of antimony: sulphur is also good in all such cases; and even crude antimony in fine powder, given with equal parts of sulphur, often succeeds in the proportion of an ounce in the morning and another at night.

The worms which infest the bodies of other animals of different domestic kinds may be destroyed, expelled, or got rid of, by the same remedies and modes of treatment, only proportioning their quantities to the nature and strength of the animals to which they may be given, and regulating the manner of exhibiting and continuing them, to that of the states in which they may be at the time, from the effects of the worms and other causes.

There is also a kind of worms which are frequently fatal

to the gallinaceous birds, of which a curious account has been given by Mr. Weinfenthal, in the Medical and Physical Journal. The inconvenience produced by these creatures is at first but slight: however, it gradually becomes more and more oppressive, until it ultimately destroys the birds. Very few indeed recover; they languish, grow dispirited, droop, and die. It is found, on dissection, that these symptoms are occasioned by worms in the trachea. The writer has seen the whole of it completely filled with these worms, and has been astonished at the animal's being capable of respiration at all under such circumstances.

They are of a reddish colour, and at first view resemble the human lumbricus; but when examined are materially different. When exposed to the microscope, they are found to have an orifice or mouth at one end, formed for suction; the other end, as far as it can be ascertained, is imperforated. The intestinal tube is much convoluted, like that of the lumbricus.

It does not appear that any effectual remedy has been yet discovered for removing these most destructive animals. They have been drawn out of the trachea by means of a feather, stripped from near its end, which is passed into the larynx and twisted round, till it engages one or two of the worms, which are extracted, but without any relief to the animal, after the operation has been performed.

WORM, in *Timber*, a disease in growing fir, and perhaps other timber-trees, produced by a worm. For which it is supposed by Mr. Nicol, in his "Practical Planter," that there can be no remedy except in the draining and improvement of the soil. Indeed, this disease is not known on soils congenial to the nature of the plant; nor does it ever appear until the tree becomes sickly, by its roots having touched a cankering bottom.

It has been supposed this worm is the same with that which is found in deal, and some other sorts of wood.

WORMS, *Aquatic*. See *Water-Worms infra*.

WORM, *Ascaris*, in the *Linnean System*, a genus of the order of *intestina*, and class of *vermes*; the characters of which are, that the body is round and filiform, and attenuated towards both ends. There are two species. See ASCARIDES.

WORM, *Bee*. See *Generation of BEES*.

WORM, *Butterfly*. See AURELIA, and CATERPILLAR.

WORM, *Canker*. See SCARABÆUS.

WORM, *Chur*. See GRILLUS.

WORM, *Cochineal*. See COCTUS.

WORM, *Connough*, or *Connaught*, in *Natural History*, a name given by the common people of Ireland to a kind of caterpillar found in many parts of that kingdom; and, from its ugly aspect, reputed to be poisonous.

It is said to be the only poisonous creature of that kingdom, and many mischievous effects are attributed to its sting, and to its poisonous quality, when eaten by cattle. As to the first of these opinions, it is evidently erroneous; the creature having no power to sting at all. The other is not so easily proved false, but is much to be suspected. The reasons on which it is founded are these: the cattle in Ireland are subject to a very terrible disease, which is most frequent in autumn; about the time when these animals are in the greatest plenty.

It is most frequent also among those cattle which feed in low and marshy grounds, where this creature lives and feeds; cows and hogs, which feed in these places, are the only creatures subject to the distemper, and this is imputed to the cow's eating by large mouthfuls, because she chews the cud a second time; and the hogs feeding so foul and greedily, as to eat things which other creatures refuse. Finally, the

great cause of assigning this disease to this creature is, that the worm only appears in great numbers about once in seven years; and in these, and these years only it is, that the distemper among the cattle is common.

The symptoms by which this disease is distinguished from all others are, great swelling of the head, and a falling down of the anus; the gut often hanging out to the length of six or seven inches. The common cure among the more intelligent people is a strong decoction of the plant called bear's-foot, or great black hellebore, with some rue and garlic given with butter and beer; this is found to have great success with the cows. The hogs are cured only by mixing redde, or the common red ochre powdered, with butter-milk, and making them eat a large quantity of it.

The Irish peasants have recourse to many idle remedies; but these are found often of real service. The caterpillar, supposed to occasion this disease, feeds on the common ragwort, and is larger than most other creatures of this kind, being of the length and thickness of a man's finger; it is marked with two large spots behind the head, which are supposed by the vulgar to be the eyes, but are only round variegations, of the nature of those common on other caterpillars; and what they take to be a sting in the tail, is no other than a horn in that part, which is not peculiar to this caterpillar, but found on many others. That the common people are deceived in regard to the external parts of this creature is evident; but experiments are required yet to prove whether or not they are so, in regard to its poisonous quality.

One trial is remarked by Mr. Molyneux to have been made on a dog, who eating the skin of only one of the creatures was found dead about three days after; another dog, which drank the juices expressed from that skin, received no hurt. The insect is described in Lister's edition, under the name of the elephant caterpillar. Phil. Trans. N^o 168. p. 880.

WORM, *Earth, lumbricus*, a genus of the order of *intestina*, including two species. See EARTH-Worm and LUMBRICUS.

WORM, *Flower-root*. See FLOWER.

WORM, *Fly*, in *Natural History*, the worm or maggot produced of the egg of a fly, and afterwards to be transformed into one.

These worms are to the fly, what the caterpillar is to the butterfly it produces. The custom of the world has appropriated the term caterpillar to that one species of the flying insects' first state; but we have unfortunately no term of distinction yet established for any of the first state of any of the other flying insects, the creature produced by the egg of the fly scarce being indeterminately called worm. Till more expressive names shall be invented for these, it may not be improper to distinguish those of the different classes by the additional name of the insect they are to be changed into, and to call that which is to become a beetle, the *scarab-worm*; that which is to be hereafter a fly, the *fly-worm*; and so of the rest.

Those which are to be hereafter winged creatures of the fly-class are extremely different one from another in form and figure, and may very properly be arranged into several classes.

The most remarkable and striking differences between the classes of those creatures, are those of the form and shape of their heads. Many of them have heads which it is not easy to distinguish to be such, as they carry no one mark of the head of an animal visibly about them. There are many whose heads are variable at the pleasure of the creature, and which at times are seen to be more or less long, more or less thick, more or less flat, more or less shortened at pleasure

by the animal, and easily bent and turned about in any direction. The heads of these creatures are composed of a very soft and flexible flesh.

There are others whose heads are hard, and which always retain the same regular figure. The first general arrangement of these worms may be into those which have a variable, and those which have an invariable head. The subordinate distinctions may be deduced from the number, disposition, structure, and form of the other parts. Some worms of this kind have no legs; those of others are membranous or scaly; and others have them both membranous and scaly. Some worms have the power of altering the figures of their bodies at pleasure, both as to length and bulk: the bodies of others are rigid, and incapable of these changes. Some, again, have a thin membranous coat; whereas that of others is firm and scaly, or crustaceous. Moreover, considerable differences are observable with regard to the position, number, and figure, of their organs of respiration.

Among the fly-worms of variable heads, the disposition of the stigmata, or air-holes, at which the tracheæ of these animals terminate, will afford several distinctions of genera: *e. gr.* the worms of the common flesh-fly has in its stigmata six apertures, three in each, resembling button-holes; but the worms of many other flies have only one small eminence in each: others have them cylindrical and hollow, and projecting like horns, of which some have two, and others three, differently situated and disposed. The number and figure of the hooks, which serve these creatures for teeth, may also serve for matter of distinction. The common worm of the flesh-fly has two hooks, with a dart between them; others have hooks without a dart; some have one hook, and others none. The figure of the body, and the differences of size and colour, may furnish farther distinctions with regard to the genera of the first class.

Those of the second class, which have variable heads, and differ from the former in having legs like those of the caterpillar class, have often a sort of hooks fastened to them: they have also a long fleshy tail, capable of being lengthened or contracted at pleasure, and resembling the tail of a rat; whence these are called *rat-tailed worms*. In these worms, the tail is the principal organ of respiration; its end being always open, and supplying the office of the stigmata of the other genera.

The fly-worms of the third class, which have invariable heads, and have nothing analogous to the organization of moveable jaws, have pointed heads, or such as seem truncated, and no scaly legs: these form a very numerous family both in the terrestrial and aquatic kingdom, and all of them furnish two-winged flies. Under this class Reaumur enumerates and describes eight genera. This ingenious writer mentions worms of another class, which usually produce four-winged flies, having heads of an invariable figure, and two teeth or moveable jaws near the aperture of the mouth, without scaly legs, and with the stigmata placed on the sides of their bodies. The flies produced from these are, the bees, wasps, ichneumons, gall-flies, &c. There is another class of the hexapode, or six-legged worms, which are transformed into some species of the libellæ; which have no mouth, but two openings at the top of their antennæ, through which their aliment may pass. The *formica leo*, and the puceron eaters, belong to this class. There is another class, which have bodies like those of the caterpillar class, and six legs, besides two other shorter legs or hooks near their hinder part, which serve for motion and for fixing themselves. The water-worms, which make for themselves cases of different materials, and are transformed into papi-

lionaceous flies, are of this class. There is also a class of worms, called false or bastard caterpillars. See FAUSSE *Chenille*. See the more particular description of these classes, and their subordinate genera, in Reaumur's Hist. Inf. tom. iv. p. 161, &c.

WORM, *Gourd*, the name of a species of *tenia*, or tape-worm; the body of which is of an oblong form, flat on the belly, and rounded on the back; its skin is soft, and its mouth large, horizontal, and emarginated, or dented in the middle. It resembles the common gourd in figure, and from thence has got this name of *vermis cucurbitinus*, or the gourd-worm. It is frequently found in the intestines of animals.

WORM, *Golden*. See APHRODITA.

WORM, *Guinea*, or *Hair-WORM*. See CHÆTIA, AMPHIBÆNA, and DRACUNCULI.

WORM, *Gally*, *Glow*, *Gnat*, *Gooseberry*, *Hay*, *Horse*, *Lysimachia*, *Mushroom*, *Oyster*, *Pile*, *Sheep-nose*, *Silk*, *Solitary*, and *Truffle*. See the respective articles.

WORMS, *Meal*. There are two very different insects found in our meal or flour; the one is so small, that it is only to be seen by the microscope; all that the naked eye can discover of it is, that something is alive in the place, from the whole substance of the flour being in motion. See FLOUR.

The other meal-worm is larger, and more frequently offers itself to our observation: it consists of eleven rings, and has three pair of legs. The mouth of this worm is made into a kind of forceps, and from this arise, on each side, a great number of small spinulæ; these serve instead of teeth, and the animal feeds by means of them. They are found sometimes very soft and tender, sometimes hard and firm; at some seasons they are very brisk and lively, at others they have scarce any life in them.

The most remarkable thing in regard to these worms is, that they are always exactly of the colour of the flour which they live among. Ray has observed, that the white flour breeds white ones; the coarser flour breeds larger and greyer ones; and that flour which has the bran among it, breeds brown ones of the same colour with that of itself. This is a provision of nature for the safety of the animal, since were it of a colour different from that of the flour, it must be easily discovered among it, and would be picked out and thrown away. The caterpillar tribe are thus preserved, by being of the colour of the leaves they feed on; their green usually suiting itself exactly to that of the tree or plant. Deslandes, Trait. Physf.

WORMS of the *Sea*. The sea-worms are of the number of those animals which, with the oyster and several other shell-fish, furnish us an instance of animals which remain all their lives fixed in the manner of plants to one spot, whence there is no probability of their moving themselves.

These worms are included in a sort of cases or pipes, and may be divided into two classes, according to the nature of those cases. In the one species these only are made of grains of sand, fragments of shells, and the like, fastened together by a viscous humour; and in the other they are composed of a true shelly matter.

Those worms which have shelly cases are fixed sometimes to the sand at the bottom of the sea, sometimes to stones, or sea substances, and sometimes to the shells of other fishes; their shells are rounded, and, in some degree, conic, as they always gradually grow wider from their point or apex to the mouth; as to the rest, their shape is different in almost every individual, forming divers irregular curves, and often resembling the shapes into which a common earth-worm curls and twits itself in its various motions.

When we consider the effects of the glutinous juice issuing from the body of this animal, in fastening together any loose substances it meets with, so as to form a case for it, it may be easily supposed that the adhesion of the balani-marini, and other the like shells, which remain all their lives fixed to some one spot, is performed in the same manner. Mem. Acad. Par. 1711. See VERMICULUS.

WORMS, Water. Of these there are some which transform themselves by a singular process, without any visible change in its exterior form, into flies, and belong to the third class of fly-worms. They are particularly described by M. Reaumur, Hist. Inf. tom. iv. p. 310, &c.

There is a singular species of these creatures, which is found to be capable of reproduction or multiplication from cuttings, in the manner of the polype.

The discovery Mr. Trembley made of this strange property in the polype, gave occasion to the trying of the experiment in regard to some other insects. Worms were the most natural objects of these experiments; and though they failed in many species, they yet succeeded in some, and proved, that nature has not given that amazing property of reproduction of its most essential parts, to only one species of animals.

Mr. Bonet tried the experiment on a very nimble kind of water-worm, by cutting it into two in the middle, and the success perfectly answered the expectation; for the two pieces continued alive and vigorous, and in a little time became two complete worms. The structure of these worms, though it appear simple to the naked eye, is very worthy the examination of the microscope, and when viewed with this assistance, there are discovered in it parts extremely deserving our attention. Phil. Transf. N° 469. p. 470.

Dr. Hales, in his Vegetable Statics, relates a curious experiment, by which it is proved that the bones of animals, when they are ossified to a certain degree, do not grow any longer, except at their extremities; and the case is the same in regard to these worms; for the old piece, which is the middle of the animal, never lengthens itself, but the addition of new rings to each end makes the increase of length in the worm.

In all these pieces the liquor, which serves as blood to the animal, is found circulating from the tail-part towards the head, in the usual way; and by this motion of the blood it is always easy to know, even in the smallest pieces, which is the head and which the tail-end, and the new head and tail are always seen to come regularly from the proper ends. Phil. Transf. N° 469. p. 470, &c. See REPRODUCTION.

WORM, in Chemistry, denotes a long, winding pewter-pipe, which distillers and apothecaries place in a tub of water, to cool and condense the vapour in the distillation of spirits.

This the chemists also call a *serpentine*. Formerly, this worm, or something like it, was placed above the head of the still, with a refrigeratory at the upper end of it, which is useful enough in the distilling of spirit of wine.

WORM, in Gunnery, is a single or double-wired iron screw, mounted on a wooden handle by means of a socket, or fixed on the end of a rammer, to pull out the wad of a cannon, firelock, carabine, or pistol; it is the same with the *wad-book*, only the one is more proper for small fire-arms, and the other for cannon.

This instrument serves to draw out the wadding, or pieces of cartridges, which remain in the gun after frequent firing, and which would otherwise accumulate so much, that other cartridges could not be rammed home enough to reach the priming, whereby the gun would miss fire.

To **WORM a Cable or Hawser,** in *Sea Language*, signifies to strengthen it, by winding a small line, or rope, all along between the strands.

WORM-Powders. See POWDER.

WORM-Seed, Semen Contra, Semen Sanctum, or Semen Santonicum, is a hot, bitter, drying kind of seed, proper to destroy worms generated in a human body, and particularly in children.

This seed is light, small, oval, composed of a number of thin membranous coats, of a yellowish-green or brownish colour, easily friable on being rubbed between the fingers into a fine chaffy kind of substance, a bitter taste, and a strong smell. It must be chosen new, greenish, of a sharp, bitter, aromatic taste, not a little disagreeable.

The place where it is produced is Persia, about the frontiers of Muscovy. It is brought to us from Aleppo, &c. Naturalists have not been agreed about the plant that produces it.

J. Bauhine has a large dissertation on the subject. Some will have it the species of absinthium, or wormwood, called *santonicum*, or *marinum absinthium*; others will have it the *tanacetum*; others the *abrotanum*; but it is now supposed to be the produce of a species of *artemisia*, resembling in its general appearance our fine-leaved mugwort, called by Linnæus *artemisia santonica*, and the *artemisia austriaca* of Jacquin.

M. Tournefort gives us the following account of this notable drug, in the second volume of his Travels. The fementine, or worm-powder, is not gathered like our seeds. The plant grows in the meadows, and must be let ripen; and the mischief is, that as it grows near to maturity, the wind scatters a good part of it among the grass, where it is lost; and this makes it so dear.

As they dare not touch it with the hand, for fear of making it spoil the sooner, when they would gather what is left in the ear, they have recourse to this expedient. They take two hand-baskets, and, walking along the meadows, sweep the baskets, the one from right to left, the other from left to right, as if they were mowing; by this means the seed is shaken out into the baskets.

These seeds have been chiefly recommended as anthelmintics, and commonly taken, in this intention, either along with molasses, or candied with sugar. For other purposes they appear to be a strong bitter. They give out their virtue both to water and spirit. The extract made by rectified spirits, appears to be the most eligible preparation of the santonicum for the purposes of an anthelmintic; and the watery extract, or a tincture drawn from it, for the more general intentions of bitter medicines.

Some have ascribed their quality of destroying worms solely to their bitterness; but it appears from Baglini, that worms (*lumbri*) immersed in a strong infusion of these seeds were killed in five, and according to Redi seven or eight hours; while in the infusion of wormwood, and in that of agaric, the worms continued to live more than thirty hours; and hence it has been inferred, that their vermifuge effects would not wholly depend upon the bitterness of this seed. To adults, the dose in substance is from one to two drachms in a day. (Woodville's Med. Bot.) The worm-seeds of former pharmacopœias are now properly rejected, as their place is supplied by anthelmintics of more certain efficacy.

WORM-Tincture, in *Chemistry*, a name given by many to a medicine prepared by Hoffmann from earth-worms; and in many parts of Germany esteemed one of the most noted medicines in the world, though less known in other places.

The preparation is this: the worms are to be collected in the spring or summer months, and the larger sort are the best. They are to be carefully dried, and reduced to a fine powder; this powder is to be mixed up into the consistence of a poultice, with oil of tartar *per deliquium*, and this is to stand twenty-four hours; then spirit of wine is to be poured on it, so as to reach three fingers-breadth above it, and a drachm of saffron, and half a drachm of castor, are to be added, and the whole is to stand three days in infusion, and after this be filtered off for use. Some add a small quantity of opium to the tincture, but as it is often wanted in cases where opium is not proper, it is better to keep it separate thus made; and when there is occasion to have it opiated, to add as many drops of laudanum as is judged necessary.

The oil of tartar in this case penetrates the very innermost structure of the worms, and is a means of extracting such a tincture from them, as no art could otherwise contrive to make; and the medicine becomes, according to Hoffmann, much more than an anodyne, from the admixture of the salt of tartar in the tincture.

When it is intended to be made with opium, it is always proper to add also some of the hound's-tongue root, which is found as an anodyne to emulate the virtues of opium.

This tincture, whichever way prepared, is excellent in abating the pains of diseases that do not admit a cure. The fits of the gout are rendered easier by every dose of it; and even in cancers, the pain is quieted in a wonderful manner by it, and life rendered much more supportable. Hoffmann's Act. Laborator. Chym.

WORMS, in *Geography*, late a bishopric of Germany, in the circle of the Upper Rhine, surrounded by the Lower Palatinate, the county of Katzenelnbogen, and the electorate of Mentz; about ten miles in length along the borders of the Rhine. In ancient times, the Vangiones inhabited this district. In the middle ages it was called "Wormbvfeld," "Wormatzfeld," or "Wormsergau;" and one of the bishops, named Victor, is said to have assisted at a council at Cologne, in the year 347. Of the ancient bishops here, however, we have little certainty. The series of the prelates of Worms, which may be most depended on, begins with Erembert, who was appointed bishop thereof about the year 770. The bishop of Worms was subject to the archbishopric of Mentz. In the circle of the Upper Rhine, he was the summoning prince and director. In the council of the princes of the empire, he exchanged place on the spiritual bench with the elector of Wurzburg. The whole of the bishopric situated on the left side of the Rhine is annexed to France, and included in the department of Mont Tonnerre.

WORMS, a town of France, in the department of Mont Tonnerre, late an imperial city of Germany, in the circle of the Upper Rhine, and capital of a bishopric of the same name, anciently the capital of the Vangiones. It was situated nearly in the centre of the diocese to which it gave name, not far from the Rhine, and near the place where the Eisbach and Gießenbach fall into it. This city was accounted one of the free Lutheran imperial cities, with toleration and freedom of worship to the Catholics. The Calvinists had also a church here. To the Catholics belonged not only the cathedral, but likewise four collegiate and the like number of parish churches in or near the city, a college, a gymnasium, three convents, and three nunneries. The bishop's palace here was built quite new, in 1719, at the expense of bishop Francis Louis. The kings of the Franks appointed counts and dukes over it. From time immemorial it has been termed a free imperial city, and is so styled in some records of the emperor Charles IV.,

bearing date in 1355 and 1356, and in the register of the cities of 1386, and was also acknowledged such in 1479, in the diet at Nuremberg; and by the emperor Maximilian I., in formal instruments of 1507 and 1508. In 1495, 1521, 1545, and 1578, diets were held here, and this was the place in which the reformation began in 1525. In 1743, a treaty was concluded here betwixt his Britannic majesty, the queen of Hungary, and the king of Sardinia. In the beginning of the revolution, Worms surrendered to a detachment of the French republican army, and was laid under a heavy contribution by Custine, but evacuated after the loss of Mentz. It was again taken in 1794; 25 miles S. of Mentz. N. lat. 49° 36'. E. long. 8° 22'.

WORMS. See BORMIO.

WORMS's Head, or *Penrhyn Gwyr*, a rock on the south coast of Wales, in the county of Glamorgan. N. lat. 51° 36'. W. long. 4° 17'.

WORMSDORF, a town of Saxony, in the circle of Leipzig; 20 miles E. of Leipzig. N. lat. 51° 16'. E. long. 12° 53'.

WORMSER JOCH, a mountain of the Tyrolse, between the sources of the Adige and the Adda; 8 miles S. of Glurentz.

WORMVILLE, a town of United America, in the Mississippi territory.

WORMWOOD, ABSINTHIUM, in *Botany*. See ARTEMISIA *Absinthium*.

The common wormwood, *artemisia absinthium* of Linnæus, grows wild about dunghills, and on dry waste grounds, flowers in June or July, and may be propagated by slips in March or October, or raised from seeds sown soon after they are ripe. The leaves have a strong offensive smell, and a very bitter nauseous taste; the flowers are equally bitter, but less nauseous; the roots are warm and aromatic, without the bitterness and offensiveness of the other parts: the leaves lose part of their ill smell by being dried and kept for some time. The active parts of this plant seem to be extractive, essential oil, and a small portion of resin.

Wormwood leaves give out nearly the whole of their smell and taste both to aqueous and spirituous menstrua; the former, prepared without heat, being the least ungrateful. Rectified spirit elevates little from this plant in distillation; water brings over nearly the whole of its smell and flavour. Along with the aqueous fluid there arises an essential oil, which smells strongly, and tastes nauseously of the wormwood, though not bitter. The oil drawn from the fresh herb is commonly of a dark green; from the dry, of a deep yellowish-brown colour. The quantity of oil varies according to the season and soil in which the wormwood is produced: in some years, ten pounds have afforded upwards of two ounces; in others, twenty pounds have yielded little more than one ounce. Geoffroy observes (Mem. Acad. Par. 1721), that in rainy seasons and moist soils, it yields the most oil; that in dry years the oil is accompanied with a resinous matter, and proves of a fine green colour; and that in wet seasons it is less resinous, and not green. A decoction of wormwood in water, long boiled, and inspissated to the consistence of an extract, loses the smell and flavour of the plant, but retains its bitterness. An extract, made with rectified spirit, contains, along with the bitter, nearly the whole of the nauseous part; the watery extract gives out its simple bitterness, not only to water again, but to rectified spirit.

Wormwood is a moderately warm stomachic and corroborant: for these intentions it was formerly in common use, but it has now given place to bitters of a less ungrateful kind. An infusion of the leaves, with the addition of fixed

WORMWOOD.

alkaline salt, is a powerful diuretic in dropical cafes. The essential oil is sometimes given, in doses of a drop or two, properly diluted by solution in spirit of wine, as a mild antispasmodic. Its more frequent use is a vermifuge; for which purpose it is both applied to the belly, and taken in pills made with crumb of bread. Dr. Lewis, however, says, that the spirituous extract promises to be, in this intention, preferable to the pure oil; as it contains, along with the oil, all the bitter matter of the wormwood. This plant very powerfully resists putrefaction, and is made a principal ingredient in antiseptic fomentations. Boerhaave commends, in tertian agues, a medicated liquor, prepared by grinding about seven grains of the oil with a drachm of sugar, and two drachms of the alkaline salt extracted from the ashes of wormwood, and afterwards dissolving the compound in six ounces of the distilled water of the plant. Two hours before the fit is expected, the patient is to bathe his feet and legs in warm water, and then drink half an ounce of the liquor every quarter of an hour, till the two hours are expired: by this means, he says, cafes of this kind are generally cured with ease and safety, provided there is no feirrhosity or suppuration.

Dr. Lewis observes, that this medicine is a very serviceable aperient, where obstructions of the viscera prohibit the immediate use of the bark, and in such obstructions as the imprudent use of the bark may have occasioned. Its virtues, he says, might be improved by an addition of the bitter watery extract; though the compound, thus laboriously prepared, would not be at all superior to a simple infusion of the plant in pure water, impregnated with a due proportion of fixed alkaline salt.

The roots of wormwood, says Dr. Lewis, promise to be applicable to some useful purposes: their virtue resides chiefly in the cortical part; and rectified spirit extracts their flavour more perfectly than watery liquors. The Edinburgh college directs a tincture of the dried flowering tops of wormwood, in the proportion of six ounces to a quart of rectified spirit, under the title of *tinctura absinthii*. This, in the opinion of Dr. Cullen, is a light and agreeable bitter, and at the same time a strong impregnation of the wormwood. Dr. Cullen concurs with Bergius and Gladitsch in ascribing to the odour of wormwood a quality of occasioning some confusion of the head; and formerly, he says, when it was the fashion with some people in the country to drink purl, that is, ale in which wormwood is infused, it was commonly alleged to be more intoxicating than other ales. This effect he inclines to attribute to its narcotic power; and he is of opinion, that there is in every bitter, when largely employed, a power of destroying the sensibility and irritability of the nervous power. The dose in substance may be ℥j to ℥ij, and of the infusion, made by macerating ℥vj of the plant in f̄xxij of water, f̄j to f̄xxij three or four times a day. Lewis's Mat. Med. Woodville's Med. Bot.

The ashes of wormwood afford a more pure alkaline salt than most other vegetables, excepting bean-stalks, broom, and the larger trees. In the Amcen. Acad. vol. ii. p. 160. Linnæus mentions two cafes, in which an essence, prepared from this plant, and taken for a considerable time, prevented the formation of stones in the kidneys or bladder; the patients forbearing the use of wine and acids.

Many nauseous insects are destroyed or driven away by the smell of this plant; and it is no uncommon practice among the good women in the country, to preserve their clothes from moths, by laying bundles of dried wormwood among them.

Some of our brewers have a method of using wormwood instead of the hops, to give the bitter taste to their malt-liquors, and to preserve them. It is found to answer the latter purpose very well; but the taste is so disagreeable, that it is much complained of. The reason of this is, that the people who use it do not understand the time of gathering it.

All plants are fullest of juice while in the shoot, but fullest of virtue when they have their seeds on them. This is the case with wormwood, as well as a thousand others; and though, in the feeding-time, it produces much more flavour than when younger, yet it is without that nauseous bitter of the crude juice, which gives us the distaste to the plant.

Some people have found the proper way of managing wormwood; and have given a flavour with it to their malt-liquors, even preferable, in the opinion of all palates, to that given in the common way by hops.

The method is this: the plant is to be gathered when fully ripe, and the seeds upon it, and in this state hung up in small bunches to dry. When thoroughly dried, a certain quantity of good strong malt-liquor is to be impregnated with it, to the utmost strength that it can possibly give it. This is to be set by for use, to add to all the rest.

When the hops should in the common way be added to the beer, this liquor is to be added in a proper quantity, making the taste the judge when there is enough of it.

By this means just what degree of bitter is required may be given to the liquor, and the bitter of this common plant, thus managed, is as perfectly agreeable as that of any vegetable in the world.

The wormwood, for this purpose, should have its seeds carefully preserved in the drying, and it is best if not used till the year after it was gathered. Phil. Transf. N° 124.

The essential salt of wormwood is afforded in great quantity, and possesses in many respects the virtues of the plant. It does not differ from other vegetable fixed alkalies, provided they be equally pure.

Wormwood shares with all other bitters the virtues of an absterfive deobstruent, and is in some degree purgative, as all bitters are. Wormwood is one of those plants which the chemists have generally chosen for their processes of the resuscitation of plants from their ashes; and though the pretended principles of this art are false, yet there have been some of the artists so cunning as to form representations of this plant, that have deceived and puzzled the greatest unbelievers, though they have not convinced them. Phil. Transf. N° 74.

WORMWOOD, *Sea*, *artemisia maritima* of Linnæus, falsely called in our markets *Roman wormwood*, and substituted for it: it is a native of Britain, and grows plentifully about our salt-marshes, and in several parts on the sea-coast, flowering in August and September. In taste and smell it is less unpleasant than the common wormwood; and hence is preferred by the college as an ingredient in some of the distilled waters; the essential oil is less ungrateful, and the watery extract less bitter than those of the common sort. The virtues are the same, differing only in degree. It is less effectual as an antiseptic and anthelmintic, but more eligible as a stomachic. A conserve of the tops, made by beating them with thrice their weight of fine sugar, is kept in the shops; but it is now scarcely ever used.

WORMWOOD, *Roman*, *artemisia pontica* of Linnæus, has more numerous, more finely divided, and darker coloured leaves than the former, and is hoary only underneath, whereas that is hoary all over. This is a foreign species, but as hardy and as easily raised as the others. It is considerably

siderably less ungrateful than either of the former species; its smell is weaker, and its bitterness is mixed with a kind of aromatic flavour. This appears to be the most eligible of the three, as a stomachic and corroborant; in which intention a conserve of the tops has been greatly recommended.

WORMWOOD, *Mountain, artemisia glacialis* of Linnæus, is fine-leaved, and covered with a glossy silk-like down. The mountain wormwood of Valais, or *absinthium seriphium montanum candidum* C. B. is covered with a cotton-like down, and the leaves are curled about the edges. Haller informs us, that the first of these plants is frequent in stony grounds on the Alps; and the second by the sides of sandy roads in the territory of Valais, in Switzerland; that the former is bitterish and aromatic, of great estimation among the inhabitants of the Alps, and the common remedy against the intermittent fevers which often rage there, and for exciting the menstrual discharges, checked by the cold; and that the latter has an acrid aromatic smell and taste, without bitterness, and promises, from its sensible qualities, to be a plant of great virtues. They have not yet been introduced into practice in this country. Lewis. See ARTEMISIA.

WORMWOOD-Tree, in *Gardening*. See ARTEMISIA.

WORMWOOD-Fly, in *Natural History*, a very small black fly, found on the stalks of the common wormwood in June and July.

WORMWOOD-Wine, *Vinum Absinthites*. See VINUM, and ABSINTHITES.

WOROFIDOW, in *Geography*, a town of Poland, in the palatinate of Braclaw; 26 miles N.E. of Braclaw.

WORONETZ, a town of Russia, in the government of Orlof, situated upon a river of the same name, near the spot where it falls into the Don, and thus possessing an easy intercourse with the Black sea. It is qualified for becoming a great capital, being placed so as to enjoy the advantages of both warm and cold climates, and holding an intercourse with all parts of the empire. The streets are wide, but not paved. Tallow is a great article of trade here, and also iron. Here is also the most considerable cloth manufactory in Russia, first established by Peter the Great: the gypsy tribe is very prevalent here.

WORPE, a river of Germany, which runs into the Wumme, 7 miles N.E. of Bremen.

WORRAL, in *Zoology*, an animal of the lizard kind, of about four feet long, and eight inches broad, with a forked tongue, which it puts out like a serpent, but without teeth.

It is a harmless animal, and feeds only on large flies, and the smaller species of lizards. It is found in Egypt only during the hottest months, and principally frequents the grottos and caverns in the mountains on the west of the Nile, where it sleeps during the winter season.

It is said to be greatly affected by music; but experiment shews this to be an erroneous opinion. Poccocke's Egypt, vol. i. p. 208.

WORSBOROUGH, in *Geography*, a village of England, in the county of York, with a medicinal spring; 3 miles S. of Barnesley.

WORSE, a river of England, which runs into the Severn, near Bridgenorth.

WORSHIP of God, *Cultus Dei*, amounts to the same with what we otherwise call religion.

This worship consists in paying a due respect, veneration, and homage to the Deity, under a certain expectation of reward. And this internal respect, &c. is to be shewn and

testified by external acts; as prayers, sacrifices, thanksgivings, &c.

The Quietists, and some other mystic divines, set aside not only all use of external worship, but even the consideration of rewards and punishments. Yet, even the heathens had a notion, that God did not require us to serve him for nought: "Dii quamobrem colendi sint," says Cicero, "non intelligo, nullo nec accepto ab illis nec sperato bono."

The school divines divide worship into divers kinds, *viz.* *latria*, that rendered to God; and *idolatria*, that rendered to idols, or images. To which the Romanists add, *dulia*, that rendered to saints; and *hyperdulia*, that to the Virgin.

Some theological writers have observed, that the Greek word *προσκυνησις*, *to worship*, is not descriptive only of the honour which is appropriated to God, but is indifferently used to signify the honour and respect which are paid to superiors of all kinds, in heaven or on earth. Accordingly, they have distinguished between *civil* and *religious* worship.

The general principles upon which the worship of God is considered as an exercise or act of religion, to which its meaning is commonly appropriated, have been already stated under the articles PRAYER and SUNDAY; and it has been illustrated in three different views of it, as private, domestic, and public. To this article we have referred the more particular consideration of public worship, as a duty of indispensable obligation, and of indisputable importance and utility. If the worship of God, says archdeacon Paley, be a duty of religion, public worship is a necessary institution; because without it, the greater part of mankind would exercise no religious worship at all. Besides, assemblies appointed for this purpose afford regularly recurring opportunities for moral and religious instruction to those who would otherwise receive no such instruction. If we advert to fact, it will be found that the general diffusion of religious knowledge among all orders of Christians, in all Protestant, and in most Christian countries, compared with the intellectual condition of barbarous nations, can be ascribed to no other cause than the regular establishment of assemblies for divine worship; in which portions of Scripture are recited and explained, or the principles of Christian erudition are so constantly taught in sermons, incorporated with liturgies, or expressed in extempore prayer, as to imprint, by the very repetition, some knowledge and memory of these subjects upon the most unqualified and careless hearer. If this practice were not observed even by those members of the community who do not so much need the assistance that is indispensable with regard to others, and sanctioned by their presence and example, we may easily foresee how soon religious assemblies would sink into contempt and disuse. This argument meets the only serious apology that can be made for absence from public worship. But even this is a very insufficient apology in another point of view, because public worship is a duty, independently of the effect of example, of universal obligation. Man is a social being; and as such enjoys many blessings which demand public acknowledgment, and is chargeable with many errors and transgressions which he ought publicly to unite with others in confessing, and is exposed to many evils which he should deprecate in common with others who are in the same fallible or mutable state with himself.

"Surely, some will say," as Paley states another objection against public worship, "I may be excused from going to church so long as I pray at home, and have no reason to doubt but that my prayers are as acceptable and efficacious in

in my closet as in a cathedral; still less can I think myself obliged to sit out a tedious sermon, in order to hear what is known already, what is better learnt from books, or suggested by meditation." They, whose qualifications and habits best supply to themselves all the effect of public ordinances, will be the last to prefer this excuse, when they advert to the general consequence of setting up such an exemption, as well as when they consider the turn which is sure to be given in the neighbourhood to their absence from public worship. You stay from church, to employ the sabbath at home in exercises and studies suited to its proper business: your next neighbour stays from church, to spend the seventh day less religiously than he passed any of the six, in a sleepy, stupid rest, or at some rendezvous of drunkenness and debauchery, and yet thinks that he is only imitating you, because you both agree in not going to church. The same consideration should over-rule many small scruples concerning the rigorous propriety of some things, which may be contained in the forms, or admitted into the administration of the public worship of our communion; for it seems impossible, that even "two or three should be gathered together" in any act of social worship, if each one require from the rest an implicit submission to his objections; and if no man will attend upon a religious service, which in any point contradicts his opinion of truth, or falls short of his ideas of perfection.

We may add, that there are other valuable advantages resulting from religious assemblies, that are not immediately designed in the institution, or contemplated by the individuals who compose them; *e. g.* 1. Joining in prayer and praises to their common Creator and governor has a sensible tendency to unite mankind together, and to cherish and enlarge the generous affections. 2. Assemblies for the purpose of divine worship, placing men under impressions, by which they are taught to consider their relation to the Deity, and to contemplate those around them with a view to that relation, force upon their thoughts the natural equality of the human species, and thereby promote humility and condescension in the highest orders of the community, and inspire the lowest with a sense of their rights. Thus, things are made to appear little, by being placed beside what is great. In which manner, superiorities, that occupy the whole field of the imagination, will vanish, or shrink to their proper diminutiveness, when compared with the distance by which even the highest of men are removed from the Supreme Being: and this comparison is naturally introduced by all acts of joint worship. If ever the poor man holds up his head, it is at church: if ever the rich man views him with respect, it is there; and both will be the better, and the public profited, the oftener they meet in a situation in which the consciousness of dignity in the one is tempered and mitigated, and the spirit of the other erected and confirmed. Moreover, the public worship of Christians is a duty of divine appointment. (Matt. xviii. 20. Heb. x. 25.) Independently of these passages of Scripture, a disciple of Christianity will hardly think himself at liberty to dispute a practice set on foot by the inspired preachers of his religion, coeval with its institution, and retained by every sect into which it has been since divided. Paley's *Philos.* vol. ii.

As to the manner in which public worship should be conducted, if we advert to the history of the primitive church, we shall find, that when the congregation was assembled, the first act of divine service which they performed was the reading of the Holy Scriptures. (See Tertullian *de Anima*, c. 3. Justin Martyr, *Apolog.* ii.) When the reading of the Scriptures was ended, then followed the singing of psalms. (See Tertullian, *ubi supra.* Pliny *Epist.* ad Trajan. Clemens Alex. *Stromat.* l. 6. Origen, *De Orat.* § 6.) The

psalms or hymns which were sung by the primitive Christians were either taken out of the Holy Scriptures, and particularly out of the book of Psalms, or such as were of their own private composition. (Tertullian, *Apolog.* c. 39.) As to their manner of singing, it was, says Origen, (*De Orat.* § 6.) in good tune and concert, all the people bearing a part in it. With respect to church-music, organs, and the like, they were not known in the primitive ages to which we now refer; for it cannot be rationally conceived that in those days of continual persecution or violence they could either use or preserve them. The singing of psalms was followed by the preaching of the word. (See Tertullian *de Anima*, c. 3.) The subject of the sermon was usually a commentary or explication of the lessons that had been just before read. (See Just. Martyr, *Apolog.* ii. Origen *contra Celsum*, lib. iii.) As for the length of the sermon, it usually lasted an hour. It began with an exordium, and then explained verse after verse, and sentence after sentence, shewing the natural and literal signification of the words, and then the spiritualized or mystical meaning of them, and concluded with a suitable application of all, either by way of exhortation to piety and virtue, or by way of dehortation from vice and impiety; always accommodating the discourse to the capacities of the hearers. (Origen *contra Celsum*, lib. iii.) The preacher was usually the bishop of the parish. (Just. Martyr, *Apolog.* ii.) Or, the bishop decreed a presbyter, or some other fit person, to preach in his room. When the sermon was finished, the congregation rose up to present their common and public prayers unto Almighty God (Just. Martyr, *Apolog.* ii.); standing being the usual posture of praying, at least the constant one on Sundays, on which days they esteemed it a sin to kneel; and the preacher frequently concluded his sermon with an exhortation to his auditors to stand up and pray to God, which is found to be the case in Origen's sermons. When the congregation stood up, all turned their faces towards the east, which was their usual custom (Tertullian, *Apolog.* c. 16.); for which practice they alleged the following reasons: 1. Respect and reverence to their lord and master Jesus Christ; this being the title given to him in the Old Testament, according to an erroneous translation of the word *branch* in the Septuagint. So that the east was called by Tertullian a type of Christ. 2. The similitude (*Zach.* vi. 12.) of the arising of the sun to our spiritual arising out of the darkness of sin and corruption, as Clem. Alex. expresses it. (*Stromat.* lib. vii.) 3. The advice of Origen to pray towards the eastern climate, as denoting our diligence in the service of God, in being more forward to arise and set about it than the sun is to run its daily course, for which he produces the authority of an Apocryphal text, *Wisdom*, xvi. 28. (Origen *de Orat.* § 20.) 4. The opinion they entertained of the excellence of this quarter above others. (Origen *de Orat.* § 21.) The congregation being thus turned towards the east, they put themselves into a posture of prayer, stretching out their hands, and lifting up their eyes towards heaven. (Clem. Alex. *Stromat.* lib. vii. Tertull. *Apolog.* c. 30.) The minister then began to pray, his usual garb being a pallium, or, as we call it, a cloak; which was deemed a more simple and plain garment than the toga, which was used through the whole Roman empire. But it does not appear from any authority of ancient writers, that they put a surplice or any other kind of linen garment over their cloaks. The prayer was pronounced, as Cyprian says (*De Orat. Domin.* § 2.), with a modest and bashful voice, that being most proper for those who came to acknowledge the multitude and heinousness of their sins, and to beg God's pardon and grace, which is the end and design of prayer. The people did not vocally join with the minister in the prayers,

but satisfied themselves with testifying their assent to what he expressed, by saying Amen, or so be it. Indeed it was impossible for the people to respond, since they had no fixed public form of prayer, except the Lord's prayer, which they frequently, though not always, repeated; and as to their other prayers, every bishop or minister of a parish was left to his own liberty or ability therein. The constant repetition of the Lord's prayer with other prayers was not thought to be necessary, but it was frequently omitted. Accordingly they regarded the Lord's prayer as given by Christ for a pattern of all other prayers, so that Cyprian (*De Unit. Eccles.* § 11.) calls it the law or rule of praying. But though the repetition of the Lord's prayer was not necessary, yet it was usual. Although they used that, they had also other prayers. Their usual method, according to Tertullian (*De Orat.*), seems to have been, first to begin with the Lord's prayer, as the ground and foundation of all others, and then, according to their circumstances and conditions, as he expresses it, to offer up their own prayers and requests. These other prayers, however, were not restricted or imposed forms; but the words and expressions of them were left to the prudence, choice, and judgment of every particular bishop or minister. In other words, the primitive Christians had no stinted liturgies, or imposed forms of prayer. As to prescribed forms, there is not the least mention of them in any of the primitive writings, nor the least word or syllable tending to it, according to lord King, which, as he says, is an unaccountable silence if there ever were such, but rather some expressions intimating the contrary; such as the minister's praying *ὅση δύναμις*, according to his ability. (*Just. Mart. Apolog. ii.* Origen, *Comment. in Matth. et in Johann.*) The noble author now cited has shewn from parallel passages, that the minister's praying *ὅση δύναμις*, or according to the utmost of his ability, imports the exercise of his gifts and parts in suitable matter and apt expressions; and that the primitive prayers were such appears farther from a passage in Origen, which explains the verse in *Matth. vi.* "When ye pray, use not mere repetitions, &c." It is very unlikely, continues his lordship, that they were obliged to prescribed forms, because they never read a syllable of their prayers out of any book whatever; which is evident from their posture of prayer, that was two-fold, either with their hands and eyes lifted up to heaven, or with their eyes shut. (*Tertull. de Orat.* Origen in *Matth. vi. 5.* *De Orat.* § 9. *Contra Celsum*, lib. vii.) If they had used prescribed and imposed forms, they must necessarily have remembered them, which would have been an intolerable load to the strongest memory; especially to have repeated, word after word, the prayers of their fast-days, which must have been several hours long, since some of their fasts were prolonged from the morning of one day to the beginning of another. Whether their prayers were divided into several collects, our author has not been able positively to determine; but he thinks it probable, that on their fast-days they made several distinct prayers, and that at their ordinary meetings, their prayer after sermon was but one entire piece. According to *Just. Martyr (Apolog. ii.)*, the prayer that preceded the confirmation of the eucharistical elements "was one long prayer, to which the people said, Amen." *Lord King's Enquiry into the Constitution, Discipline, Unity, and Worship of the Primitive Church*, part ii. See **LITURGY**.

WORSLEY, in *Geography*, a populous township in the parish of Eccles, and county of Lancaster, England, 6 miles W.N.W. from the town of Manchester. In the year 1811, this place contained 6151 inhabitants, who occupied 1012 houses; and nearly the whole of whom were engaged in manufactures and the coal-mines. At this place is the

famous tunnel for the Bridgewater canal, (see **CANAL**,) and a large brick mansion, called **Worsley-hall**, which belonged to, and was inhabited by, the late duke of Bridgewater. See *Lancashire Gazetteer*, 1808.

WORSTED, or **WORSTED**, a market-town in the hundred of Tunstead, and county of Norfolk, England, is situated 4 miles S.S.E. from North Walsham, and 120 miles N.E. by N. from London. It was formerly a place of much celebrity, and of considerable trade; but is now greatly on the decline, and is chiefly remarkable for the invention, or first twisting, of that sort of woollen yarn or thread, which hence obtained the name of worsted. This manufacture is mentioned in the second year of Edward III. when the weavers and workers of worsted stuffs were required by parliament to work them in a better manner than they had previously done. These stuffs, and knit and wove hose, constitute the chief manufacture of the town. A weekly market is held on Saturdays, and here is an annual fair. The church consists of a nave, two aisles, a chancel, and a square tower. The population of the parish, according to the return of the year 1811, amounted to 619, occupying 112 houses.

Contiguous to the town is **Worsted-hall**, the seat of sir George Berney Brograve, bart., a commodious mansion, situated in a pleasant park.—*Beauties of England and Wales*, vol. xi. Norfolk; by J. Britton, F.S.A. 1809. *Blomefield's History of Norfolk*, vol. xi. 1810.

WORSTED, and **WORSTED Manufacture**. The term worsted is applied to yarn, and manufactured goods made of combed wool. Worsted is properly a branch of the *Woollen Manufacture*, to which article we refer our readers; but the latter term, strictly speaking, is applied only to yarn, or pieces made entirely or in part of carded wool. The characteristic distinction between combing-wool and short or clothing-wool has been already stated under the article **WOOL**. (See **WOOL** and **WOOLLEN Manufacture**.) Worsted goods were made in England as early as the time of Edward II. In the account of exports in the following reign, already given in the article **WOOLLEN Manufacture**, the number of pieces of worsted goods exported is nearly double that of woollen cloths. According to Camden, the name is derived from **Worsted**, a town in Norfolk, where worsted stuffs were first made. According to Dr. Parry, in his "Essay on the Merino Breed of Sheep," worsteds were called by the Flemings '*Ostades*,' and as the manufacture was in their hands long before it was introduced into England, it is probable that our appellation is a corruption of their's. *Ostade* was long ago a common surname in Flanders, and was perhaps that of some person famous for this particular branch of the woollen trade, which afterwards was appropriated to an establishment of similar manufacturers in Norfolk.

Worsted yarn is made of long or combing-wool, in which the fibres are all laid even parallel with each other by the wool-comb. It may be classed into two great divisions, the soft and the hard worsted yarn. The soft yarn is made of the shorter kinds of combing-wool, the sorting of which has been already described under the article **WOOL**. The short and long combing-wools are both prepared for spinning by the comb in the same manner, except that for some kinds of fine hard yarn made from the latter, the wool is combed, and afterwards spun nearly without oil. This is the case with the yarn for bombazines. The soft yarn for hosiery receives but little twist in the spinning, and two, three, or more threads are afterwards twined together on what is called a doubling-mill, to make a thread of requisite strength and thickness to be woven on the stocking-frame. See **STOCKING-Frame**.

WORSTED MANUFACTURE.

Knitting-yarn is twined much harder than yarn for the frame. For mixed coloured stockings, part of the wool is dyed and mixed with the white in the process of combing. The principal seats of the worsted hosiery manufacture in England were Nottingham and Leicester; but of late years the worsted hosiery has declined at the former place, the trade there being principally confined to silk and cotton articles. Formerly hosiery comprised a variety of worsted articles, particularly caps, which were generally worn in England before the introduction of hats.

At Aberdeen, in Scotland, there is a considerable manufacture of hosiery, the wool being principally supplied from London. Worsteds stockings, and lamb's-wool hosiery, to the amount of from fifty to seventy thousand pounds, are said to have been annually exported from Aberdeen to Holland. Of the number of hands employed in worsted hosiery in England, or the annual value of the goods made, we have no correct account. Perhaps some estimate may be formed from the amount of exports of woollen hosiery given under the head *Woollen Manufacture*, in the table of exports, in which it will be seen, that in the year 1816 the worsted hosiery exported amounted to one hundred and fifty-one thousand and sixty pounds. This, we believe, includes the hosiery made of woollen yarn, or what is generally called lamb's-wool yarn, an article which, since the beginning of the present century, has been greatly increasing in demand. Soft worsted yarn for hosiery, during the last twenty years, has been principally spun and doubled by machines in large worsted-mills. Previously to that time, worsted-making by hand-spinning was a distinct trade from hosiery. The worsted-maker bought his different sorts of combing-wool from the wool-stapler, combed and spun it, and sold the yarn to the hosiery. Since then, the hosiery have been principally supplied with worsted yarn from large mills established in Leicestershire, Nottinghamshire, and Warwickshire. Of late, however, many of the hosiery are manufacturing their own yarn on machines or mules turned by the hand, or in small mills turned by horses or water.

The combing-wools of Kent are better suited for hosiery worsted yarn than any other in England, particularly for machine-spinning. This excellence is derived partly from the softness as well as soundness of the wool; but particularly from the staple being nearly of one uniform thickness from the bottom to the top. See *WOOL*.

Picardy and Normandy were the principal seats of the worsted hosiery in France. Under the article *WOOLLEN Manufacture*, it will be seen that 1,250,000 pounds weight of wool were consumed annually in the manufacture of hosiery in Picardy before the French revolution.

The stocking-frame was invented by William Lee, M.A. of Cambridge, in 1589, and was afterwards introduced into France. This invention took place in England only 28 years after the knitting of hosiery yarn on needles had been introduced from Spain. See *STOCKING-FRAME*.

Hard worsted yarn for worsted stuffs or pieces is spun much smaller, and twined much harder, than the soft worsted yarn for hosiery. In all the stouter kinds of worsted goods, the long or heavy combing-wool is used. (See *WOOL*.) Under the article *WOOLLEN Manufacture* we have noticed the introduction of the worsted trade into England, and various places where it was first established. Norwich and some of the towns in Norfolk and Suffolk appear to have been the first where any considerable quantity of worsted pieces or stuffs were made. The names which the different kinds of worsted pieces have received are very numerous, being often derived from the manufacturer who introduced a slight change either in the mode of weaving or

finishing the goods. These names soon became obsolete, being supplanted by other kinds of worsted goods, so that we do not know at present to what particular kind of pieces some of them were formerly applied; the essential difference consisting in their being woven plain, twilled, or figured, or made with a warp of single or doubled yarn, and woven stouter or more slightly, or of greater or less width, and whether they were glazed or not in the finishing.

The most important distinction between worsted pieces and woollen cloth consists in the former not being milled or raised, so as to cover the surface with a pile, but the thread is left bare. To take off the loose hairs which rise from the surface, the worsted pieces are passed over a red-hot cylinder, in the same manner as many kinds of cotton (see *COTTON Manufacture*): this process is called *fining*. For some particular purposes, a slight degree of milling has recently been attempted to be given to worsted pieces in the fulling-mill. The glazing communicated to some kinds of worsted goods is given by pressing them between sheets of stiff glazed press-paper and heated iron plates, which are compressed in a strong pressing-frame. For the weaving of figured pieces, see *WEAVING*, and *DRAUGHT of Looms*.

Some kinds of very fine worsted goods are made with a warp of mohair or silk, as silk camlets and bombazines. The latter goods, with a silk warp and worsted with hard worsted yarn of the finest kind, are manufactured at Norwich. The term bombazine appears to be derived from bombycina, a kind of silk dress used by the Romans, and said to come from Assyria. It is generally understood to have been made from the threads of an insect called the bombyx. Bombycina is sometimes confounded by commentators with byssinum and sericum. Byssinum appears to have been a very fine kind of linen or lace; sericum unquestionably means filken stuff, so called from the Seres, the nation whence it was procured. Probably bombycina was a coarser kind of silk. In the middle ages, the word bombycina was applied to cotton. Macpherfon's *Annals of Commerce*. See *BYSSUS*.

Bombazines are woven with a twill, and have, as before stated, a warp of silk and a weft of fine worsted yarn. The Dutch refugees, who fled from the persecution of the duke of Alva, introduced the manufacture of this article into Norwich in the year 1675, when the Dutch elders, according to Blomefield, presented bombazines in court at Norwich. (Blomefield's *Hist. of Norfolk*, vol. ii. p. 205.) Worsteds goods were made in Norwich as early as the reign of Edward II. This appears from a patent granted to John Peacock, for the measuring every piece of worsted made in the city of Norwich or county of Norfolk. Norwich has continued from that time one of the principal seats of the worsted and stuff trade. The sale of stuffs made in Norwich only, in the reign of Henry VIII., amounted to 100,000*l.* annually, besides worsted stockings, which were computed at 60,000*l.*

Norwich is at this day the only part of England where any considerable number of the very finest stuffs and bombazines are made. The manufacture of the coarser kinds of worsteds, except camlets, has been transferred in a great measure into Yorkshire. The period preceding the American revolution, from the year 1743 to 1763, may perhaps be regarded as the most flourishing era of the worsted manufactures of Norwich. According to the account of Arthur Young in 1771, the manufactures of this place had increased four-fold in the preceding 70 years. The number of looms was then estimated at 12,000, and each loom was supposed to employ six persons in preparing and finishing the

WORSTED MANUFACTURE.

the material; and the total annual value of the goods was estimated at above 1,200,000*l.* Of these goods the estimate then was,

	£
The export to Rotterdam - -	480,000
----- to London - -	550,000
----- to various places - -	200,000
Total value -	1,230,000

The number of persons employed being from seventy to eighty thousand.

Since the time to which Arthur Young refers, the manufacturers of Norwich have engaged extensively in the trade of silk shawls and other articles, in which no worsted whatever is used. Still, however, the worsted manufactures of Norwich may be considered as in a flourishing state. The number of looms employed in worsted at the present time (1818) may be estimated at 10,000; half of which weave camlets, calimancoes, and other stuffs; and the other half bombazines, narrow and broad. The former are chiefly for home consumption, the latter for the Spanish market. The East India company take a considerable quantity of the fine camlets manufactured at Norwich.

By far the greatest part of the worsted yarn employed at Norwich is supplied by machine-spinning, from the worsted-mills in Yorkshire, Lancashire, and Durham. But some yarn still continues to be spun in the old manner, by the running-wheel, in Suffolk, Essex, Hertfordshire, and Cambridgeshire. In Norfolk alone, the use of the distaff still remains. This instrument is the most ancient of which we have any notice, either in sacred history, or the fabulous traditions of Grecian mythology handed down to us by Homer and Hesiod. It is at present vulgarly called the rock. In using it, the thread is drawn out from the end of the siver of combed wool. The motion is communicated to a rough kind of spindle, by twirling it between the right-hand and the thigh, which is suffered to continue revolving when suspended by the thread, which the spinstrefs gradually lengthens with her fingers.

In wheel-spinning, a small portion of the combed wool or siver is laid across the finger, from the centre of which, called the twitch, the thread is drawn out. About thirty years since, the counties of Norfolk, Suffolk, Hertfordshire, and Essex, not only supplied all the yarn that was wanting for the manufactures of those districts, but sent large quantities of worsted yarn to Halifax and Manchester. At present the trade is completely turned, and, as we have before stated, the greater part of the yarn used at Norwich is sent there from the northern counties of England. This change has occasioned great distress in the villages where the yarn was formerly spun, by depriving the wives and children of the cottagers of their common employment.

Until the middle of the last century, worsted goods were manufactured in considerable quantities in Warwickshire, Oxfordshire, and Northamptonshire; but about that time the extension of the worsted trade in the West Riding of Yorkshire, particularly at Halifax, Bradford, and Wakefield, gradually drew this trade in a great measure away from those counties. The manufacturers in Yorkshire, or rather the merchants who bought the worsted pieces from the manufacturers, were, however, long unacquainted with the best modes of dyeing and dressing them; they were therefore sent to London or Coventry to be finished, but afterwards they were finished in Yorkshire. The demand to Spain, Portugal, Italy, and the Levant, took off the greater part of the worsted goods manufactured at Halifax;

those manufactured round Wakefield and Bradford, consisting chiefly of tammies and shalloons, were consumed principally by England and her colonies. The Piece-hall at Halifax was first opened about the year 1780; and the intervening time, from thence to the year 1792, or the breaking out of the French war, may be regarded as the most flourishing era of the worsted trade in Yorkshire. Though the cheapness of calicoes, as an article of female dress, since the improvements in the cotton manufacture, materially abridged the sale for some kinds of worsted goods in England, this was more than compensated by the increased demand for carpets with worsted warps, and other articles of luxury, in which worsted yarn was employed.

The demand in foreign markets, from the year 1782 to 1792, for English worsted goods, greatly exceeded that of any former period; but after the breaking out of the French war, the worsted trade at Halifax began to decline. The greater part of the foreign markets being closed against us, most of the mercantile houses engaged in the export of worsted pieces were in consequence ruined or declined; the trade altogether, and many of the small manufacturers, engaging in the cotton trade. The introduction of English calicoes into Turkey and other parts tended also to lessen the regular demand for shalloons and other worsted goods, as articles of female dress, in those countries. Soon after the breaking out of the French war in 1792, the spinning of worsted by machinery was established at Bradford and the vicinity; and continuing to increase, drew round that place the manufacturers of worsted goods on the decline of the Halifax trade. Bradford is now become the principal seat of the worsted manufacture in Yorkshire; and some of the proprietors of the worsted mills, besides supplying the smaller manufacturers with yarn, employ a very great number of looms themselves, and carry on this branch of trade on a scale of extent never before known in the worsted manufacture. Within the last two years, the worsted trade has also greatly revived at Halifax.

The following are the kinds of worsted pieces at present principally made in Yorkshire.

Bombazets are woven both plain and twilled, with the warp of single thread; they were pressed, and finished without glazing: the width 22 inches, length 29 yards.

Tammies, or *durants*, with single warps twilled, and generally coarser than twilled bombazets: width from 32 to 36 inches, length 29 yards.

Shalloons are woven with a twill, and have a warp of single thread. We believe the name was derived from Châlons in France. The pieces are from 32 to 36 inches wide, and 29 yards long.

Cubicas are very fine shalloons so called.

Sayes, or *anascotts*, are twilled and made with single warps; they are of two kinds, one running 27 inches wide and 30 yards in length, the other 42 inches in width and 44 yards in length.

Moreens are woven plain and watered or embossed, and are made very stout, being principally used for furniture: their width is 28 inches, length 24 yards.

Calimancoes are woven plain and striped: width 17 inches, length 29 yards.

Camlets are both plain and twilled: width 18 inches, length 29 yards. They are shorter than bombazets, but not many are made in Yorkshire with doubled warps.

Lastings have doubled warps, sometimes of two and sometimes of three threads, and are made with great variety of patterns, either plain, twilled, or flowered, and are distinguished by different names, according to their figures and quality;

WORSTED MANUFACTURE.

quality; as prunelle, amens, (probably from Amiens in France, where they were manufactured,) and drawboys: the width 18 inches, length 30 yards.

Worsted shag, or velvet woven like corduroi and cut, is made principally at Banbury, in Oxfordshire, and at Coventry; but has been manufactured also in Yorkshire.

In the worsted manufactures of France, there were greater varieties of pieces than in England. One kind of camlet, made with a fine warp from the wool of the Angora goat and a weft of fine worsted, was remarkably beautiful; but we believe it has not been manufactured in Yorkshire or at Norwich.

For some account of the worsted manufactures of France, see *WOOLLEN Manufacture*; under which article we have given the history of the worsted manufacture as connected with the woollen, and where may be seen the number and value of the worsted pieces exported from England in the year ending January 1817. See also *long combing-wool*, under the article *WOOL*.

WORSTED Spinning. In the article *WOOL* we have given an account of the different kinds of long wool which are proper for spinning into worsted, also the manner of sorting and scouring them. This wool must be prepared for spinning by repeated combings, with a comb or heckle that is provided with a great number of long steel pins which are sharp-pointed. These points being few in number compared with the teeth of cards, they can be safely introduced between and drawn through the long fibres of the wool, in order to separate and straighten them, without materially breaking them. Another object of the combing is, to separate the short fibres which are intermixed with the long ones; for in spinning any kind of thread, it is desirable that the fibres should be all as nearly as possible of a length.

Wool-combing.—In the ordinary process of wool-combing by hand, the implements used are, 1. Two combs for each workman. 2. A post, to which either of the combs can be fixed, to support them during the operation. 3. A comb-pot, which is a small stove to heat the teeth of the combs, which is found to facilitate the combing. The combs are shewn at *fig. 1. Plate I. Woollen Manufacture*: each comb is composed of two rows of pointed steel teeth, *a* and *b*, disposed in two parallel planes. One of the rows contains longer teeth than the other. They are fixed into a wooden stock or head *c*, which is covered with horn, and has a handle *d* fixed into it, perpendicular to the planes of the rows of teeth. The rows of teeth are about seven inches long, and each row contains about twenty-four teeth. The length of the longest teeth is near twelve inches, and the shorter ones about eight inches. The teeth are made of steel, of a round figure, and regularly tapering from the base, where they are fixed into the stock, to the point, which is quite sharp. The teeth are about one-sixth of an inch in diameter at the base; and the interval between the two adjacent teeth at the base is rather less than their diameter, or one-eighth of an inch. The space between the two planes in which the teeth are disposed is about one-third of an inch at the bases of the teeth. The teeth should be straight and well-tempered, and polished. If they become crooked in working, the workman must straighten them, and set them all in a true line. The combs used for the last combing of the wool have three rows of teeth.

In the wool-comber's shop a post is fixed, as shewn by *fig. 2*, in order to support the combs occasionally during the working. An iron stem *g* is fixed fast into the post, and projects horizontally from it; the extreme end of it turns upwards with a point, which is inserted into a hole through the middle of the handle of the

comb. Also at the other end of the stem *g*, close to the post, there is a small hook *b* rivetted, which terminates with a pointed pin, situated in an horizontal direction. This point is inserted into a hole made in the end of the handle of the comb, in the direction of its length. The end of the comb-handle being first placed on the point of the hook *b*, it is let down upon the other point *g*, which, by passing through the handle, fixes the comb quite fast to the post, as shewn at *fig. 2*.

In the operation of combing wool, it is necessary to heat the teeth of the combs, in order to soften and relax the fibres of the wool, and render them more easy to work. The heat also tends to distribute the oil with which the wool is lubricated. The combs are heated in a comb-pot or stove, *fig. 3*, which is a small furnace built in brick, to inclose a fire-place, of which *A* is the door, *B* the ash-pit, and *C* the flue. Above the fire a circular cast-iron plate *aa* is placed. This is made flat, except in the central part, where there is a concavity, to obtain a better action of the fire. Immediately over the plate *a*, another plate, *bb*, is placed parallel to the former, but with a sufficient space between them to admit the teeth of the combs: several pieces of iron are placed between the two plates, to keep them at a proper distance asunder, and to divide the space into small cells proper for the combs.

In using this stove, the workman must be careful not to heat it too much, and a damper in the flue is very useful to regulate the draught; if the heat is too great, it spoils the temper of the comb-teeth, and injures the wool also. The most improved stove is heated by steam, which will give a sufficient warmth, but cannot overheat the combs.

In order to comb the wool, it is separated into handfuls, each containing near four ounces of wool, which is about a proper quantity to be combed at once. These handfuls are sprinkled with oil, and the wool is rolled in the hands to distribute it equally. The quantity of oil varies from $\frac{1}{8}$ th to $\frac{1}{4}$ th of the quantity of wool by weight. The comb is first heated by introducing the teeth into the stove, in one of the cells between the two iron plates; when it has acquired sufficient heat it is withdrawn, and another comb is put in its place. The heated comb is then fastened to the post, with its teeth pointing upwards, in order to be filled with wool; the comber takes one-half of the handful of wool in his hand, and catches it upon the teeth of the comb by throwing the wool over the points, so that they penetrate it; then by drawing the wool towards him, and at the same time downwards to the bottom of the teeth, a portion of the wool will remain in the teeth. The lock of wool is again cast upon the teeth, and drawn through them, and every time some wool remains; this is repeated as often as is necessary, until all the wool is gathered upon the teeth. The comb thus filled is placed with its points in the stove, and the wool which is upon it remains outside of the stove, but will become slightly warmed. The other comb, which was heating whilst the first was filling, is now filled in turn, in the same manner as the first, and is then put to heat with the wool upon it, and whilst this is going on, the workman occupies himself in making a handful ready for the next combing.

When both combs are properly warmed, the comber holds one of them with his left-hand over his knee, as he is seated on a low stool, and with the other comb held in his right-hand he combs the wool upon the first, by introducing the points of the teeth of one comb into the wool contained in the other, and drawing them through it; this is repeated for 14 or 15 strokes, until the fibres of the wool are separated, disentangled, and laid parallel. In combing, he directs

rects the combs sometimes with the teeth of one parallel to the teeth of the other, and sometimes with the teeth of the two combs at right angles, or in a cross direction; but in all cases he must take care to begin gradually, by introducing the points of the teeth, first into the extremity of the wool which is contained in the teeth of the comb, and then penetrating deeper into the wool at every succeeding stroke, till at last he works the combs as near as he possibly can without actually bringing their teeth in contact: without this precaution, he could not draw the comb through the wool without breaking the fibres, and tearing the wool out of the teeth of the comb; but if he proceeds cautiously, the wool will be disentangled, separated, and straightened.

During the working, he frequently changes the combs, so as to work the wool upon both combs; but as the wool will gradually accumulate upon that comb which is most worked, he manages them so that at the end of about 35 or 40 strokes nearly all the wool will be gathered upon one of the combs, and will hang from its teeth in a fair lock of straight and regular wool. This comb he puts to heat for a moment, then fixes it to the post, and proceeds to draw off the wool from the comb in a sliver. To do this, he takes hold of the wool which projects from the teeth with the fingers and thumbs of both hands, and draws it away from the teeth of the comb in a direction perpendicular to their length, without sliding it off their points: as the wool comes away, he takes fresh hold, always seizing the wool at a given distance from the teeth. A portion of the wool which consists of short fibres will not come off, because it does not reach to the place where the comb grasps the wool; it therefore remains in the teeth of the comb, and is drawn off afterwards. This short wool, which is called noil, is unfit for worsted spinning; it is composed in part of the short fibres which are naturally intermixed in the long ones, and also of the fragments of long fibres which are broken in the process of combing. The quantity of the noil depends upon the kind of wool, and also on the care with which the comb has conducted his process; but it will seldom exceed $\frac{1}{4}$ th or $\frac{1}{5}$ th of the quantity of the raw wool by weight.

The wool which is drawn off from the comb forms a continued sliver or band, the fibres of which are straight and parallel, but not sufficiently so for spinning; it is therefore combed over again, and frequently it is repeated a third time. The first combing is called hacking, and the slivers produced by it are extended five together upon a table; then holding them down with one hand, they are broken again into handfuls by drawing them with the other. These are combed again in the manner before described, but the heat given to the combs is much less. The ultimate sliver, which is drawn off from the comb the last time, should be very even, and composed of long and parallel fibres. On examining it against the light, every part should appear equally dense, without any entanglements of the fibres, for on these particulars the perfection of the spinning will in a great measure depend.

The combed wool produced from sixteen pounds of wool usually weighs eleven or eleven and a half pounds, for about two pounds are lost in washing, and the rest in noil and waste in the combing. When the combing is finished, the slivers are formed into six parcels, each containing ten or eleven slivers, which are rolled up together into a ball, and ticketed with their weight and quality, the wool-comber's mark, and wool-stapler's mark. In this state, combed wool is called tops or Jersey, and is sold to the spinners in the country, and in cottages, who spin it into worsted-thread by the simple hand spinning-wheel; but the manufacturers who spin by machinery have wool-combers

at their mills, and they usually employ combing-machines in addition.

Combing-Machines.—The first combing-machine was invented by the Rev. Edmund Cartwright. His first two patents were in 1790, and he had another in 1792; but the machine was not rendered perfect, or brought into extensive use, till a later period: and in 1802 he obtained an act of parliament to renew or extend the term of his patent. The specification which he enrolled in consequence contains drawings and descriptions of machines nearly of the same kind as those which are now in use at many of the great worsted-mills, and which we shall describe. Mr. Cartwright proposed to form the raw wool into continued slivers, by joining the pieces of wool together, and slightly twisting them, and in this state they could be presented to the combing-machine; but as this plan was not found to succeed, it was found necessary to comb the wool first by hand, in order to reduce it to slivers. This is still the common practice, and takes away great part of the advantage of the machine; but we have seen a preparing-machine for this purpose, which operated very well upon the raw wool. The inventor's name we have not learned; but the rudiments of it are to be found in Mr. Cartwright's specification of 1790.

Preparing-Machine.—The raw wool is spread upon a horizontal feeding-cloth, which is extended over two rollers, and circulates upon them: by its motion, the wool is carried forwards, and presented to a pair of fluted rollers, which draw it in. This feeding-cloth is situated at the top of the machine, at the height of about five feet from the floor, so as to allow room for the rest of the machinery beneath it. A principal part of the machinery is carried by a horizontal wheel of five feet diameter, which is mounted upon a vertical axis, and is turned rapidly round by the mill. This wheel carries four porcupines, which are small cylindrical rollers, armed with spikes or teeth rather hooked. The rollers are situated horizontally in the plane of the wheel, with their length nearly in the direction of radius. They are about seven inches in diameter, and fourteen inches long, and are fixed upon horizontal spindles, which proceed from the circumference of the great wheel nearly to its centre, one extremity of each spindle being sustained by the rim of the wheel, and the other in a support fixed to the perpendicular axis. The porcupines are fixed on the ends of the spindles, near the circumference of the wheel, and on the opposite end of each spindle is a small cog-wheel, to work in a worm or endless screw, which is fixed concentric with the axis, being cut on the outside of a hollow tube, through which the vertical axis passes.

By this means, the four porcupines which the wheel contains have a two-fold motion, *viz.* they are all carried round in a circle by the motion of the wheel, and at the same time each one has a slow rotative motion on its own axis, in consequence of the cog-wheels, which work in the threads of the fixed worm.

The feeding-cloth is so situated, that the four porcupines in the great wheel will pass in succession exactly beneath the fluted rollers, which take the wool from the feeding-cloth, and the teeth of the four porcupines being sharp-pointed and rather bent forwards at the points, they penetrate and catch the wool as it comes through these fluted rollers, and hangs down from them. A portion of wool is thus carried away by each porcupine every time it passes beneath the fluted rollers; but by the slow revolving motion of the porcupines on their own axes, each one presents a different row of teeth every time, and thus by degrees they become clothed with the wool which they take up.

WORSTED MANUFACTURE.

This wool they deliver to a larger porcupine, which is placed beneath the revolving-wheel, or on the opposite side to the feeding-cloth. This porcupine is a cylinder nineteen inches diameter, and fourteen inches long: its axis is placed horizontally, and directed nearly to the centre of the vertical axis; so that the small porcupines will be parallel to the large one when they pass over it. The great porcupine is furnished with rows of teeth exactly similar to those of the small ones, which teeth are not very numerous, but large and sharp-pointed, and rather hooked, with the points forwards. When the small porcupines pass over the large one, there is so little clear space between their teeth, that the wool which is contained in the teeth of the small ones will be taken off by the large one, and remain in its teeth. The reason of this is, that the teeth of the large porcupine present themselves to the teeth of the small ones with the points forwards, and the small porcupines at the same time move with the points of their teeth backwards. It was before stated, that the porcupines move with the points forwards when they take the wool from the feeding-rollers, but this wool is applied on the upper side of the porcupines, and the great porcupine is at the lower side; hence the direction of the teeth is reverse in the two cases, and occasions the wool to be given to the great porcupine, a small quantity at a time, from each of the small porcupines, as they pass over it. The great porcupine being turned slowly round upon its axis clothes itself with the wool in a continued fleece, and this is drawn off from its teeth by a pair of fluted rollers, between which it passes in a continued sliver or band; this band is also conducted through a short tube, which revolves round its axis, and rolls up the sliver, to make it adhere better together in a round and compact form.

The action of this machine is not to comb the wool, but to divide the mass of raw wool, which is spread on the feeding-cloth, into a great number of small and equal portions by the successive strokes of the small porcupines; these portions are again mixed together in one film of wool upon the great porcupine, from which the wool is drawn off in a continued sliver, and as much twist is given to it as is requisite to make the sliver sufficiently compact to submit it to the combing-machine.

Cartwright's Combing-Machine, or Combing-Table; called also amongst the workmen *Big Ben*.—In *Plate II. fig. 1. Worsted Spinning*, is a horizontal plan of the machine, which exhibits nearly all its parts; we have also given a perspective view in *fig. 2.* of the operative parts, as they would appear if detached from the framing which sustains them. *AA* is a circular ring of wood, which is fixed down on the framing; *BB* is a similar ring, which is fitted into the fixed ring, with liberty to turn round within it. The interior of this ring is furnished with a row of comb-teeth, with the points directed to the centre, and there are two other rows of shorter teeth beneath, so as to make three circular rows of teeth. This forms a large circular comb, called the combing-table, about five feet diameter; it is moved slowly round in the direction of the arrow by means of a pinion, which works into a ring of cogs, fixed in segments within side of the circular comb beneath the row of teeth, as is shewn in the section, *fig. 3.*

The wool is filled upon the teeth of the circular comb by means of two machines *F* and *G*, called crank-lashers. These supply the wool by lashing or throwing the lock of wool upon the teeth of the comb, and then drawing up the wool from the comb, with a motion very similar to that of the hand of the workman in filling the combs, as we have before described. The crank-lashers repeat their strokes with great rapidity; but as the comb-table is kept in con-

tinual motion, the wool which is lashed upon the teeth by the first crank-lasher *F* is carried away, and in its course comes beneath the other crank-lasher *G*, by which more wool is filled upon the teeth, and they receive the intended portion. This wool, by the rotation of the comb-table, is then carried beneath a small comb *K*, which works by a crank movement, but with its teeth always horizontal; they penetrate through the wool, and then rise up so as to comb it. After this operation, the wool is taken off from the teeth of the comb-table between a double pair of fluted rollers *N*, situated immediately over the comb-teeth; these draw off the combed wool in a continued sliver, which is conducted through another pair of plain rollers *R*, and falls into a tin can placed there to receive it.

This machine was not found capable of combing the raw wool, chiefly because the comb-teeth are not heated, and also because the actions of lashing on the wool, and afterwards combing it, begin to act upon wool, at first with their full force, and break the fibres if they are entangled together; hence it is found best to comb the wool by hand once over, or for fine goods twice. The wool is thus formed into slivers, which are joined together, by laying them on a table, with the ends lapped over each other; and rolling them together, they will join into one long sliver. Three of these slivers are put into tin cans *ii*, which are placed upon a circular table *I*, and carried upwards to the crank-lasher *F* or *G*, which are both of similar construction. The table *I* is mounted on an axis, so as to be capable of turning slowly round horizontally, in order to twist the three slivers together into one; but in the machines which we have seen in use, this movement is commonly neglected, for if the slivers are prepared by hand-combing, as we have before described, they will hang together without twisting.

The slivers, which are carried up from the cans to the crank-lasher (see *fig. 3.*), first pass over a roller at *e*; the axle of this roller is also the fixed centre of motion of a trough *H*, which forms one part of the crank-lasher. The sliver of wool is conducted along the trough *H*, and then turns over a second roller at *f*; the centre-pin of this roller is the joint, which unites the end of the trough *H* with a moveable frame *dd*, which has a tube *g* fixed in front for the sliver of wool to pass through. A little below the middle of this frame *dd* are holes through its sides, to receive the pin of a crank *bb*, of which the central axis is supported in bearings secured to the frame of the machine, and it is turned round by the power of the mill. By means of a pair of bevelled wheels *D* and *E*, *fig. 1.* the cranks of the two crank-lashers are connected together, and have a common motion, but in a direction at right angles to each other. At the lower end of each of the moving frames *dd*, a pair of fluted rollers *i* are fixed, which draw the sliver between them. The rollers are put in motion by means of a cog-wheel *k*, fixed on the extremity of the axis of the lower roller; this is turned by a small pinion, fixed at the end of an axis, which passes through the frame *dd*, and which at the opposite end has a wheel *h*, that receives motion from a pinion fixed fast to the pin of the crank. The upper of the two fluted rollers is pressed down against the lower one by springs, which bear on its pivots with sufficient force to hold the wool firmly between them, and draw the sliver forwards when they turn round.

The motions of the crank-lasher are not easy to be understood from a verbal description. It must be recollected, that the upper end of the frame *dd* which carries the rollers, being jointed to the end of the trough *H*, it must always move in the arch of a circle, as shewn by the dotted lines, *fig. 3*; the centre of this arch is *e*: also that the middle part of the frame *d*, where the crank-pin passes through it,

it, must describe a circle when the crank revolves: in consequence, the rollers *i*, which are at the lower end of the frame, will move in a curve, as shewn by the dotted lines. It is an oval or distorted ellipsis, with the longest diameter horizontal.

At the same time the fluted rollers circulate in this orbit, they are in continual motion on their own axis, by the communication of wheel-work before described, and they draw the sliver of wool down the tube *g*; the end of the sliver, which projects from below the rollers, hangs down from them in a lock, and by the motion of the crank-lasher this is thrown against the points of the teeth in the comb-table. At the period when the wool is thus thrown on the teeth, the rollers are moving nearly in an horizontal direction, so as to draw the wool in the direction of the length of the teeth, and they penetrate the wool; but as the rollers proceed in their elliptic orbit, they begin to rise and draw the wool upwards away from the teeth in an inclined direction, as is evident by tracing the dotted course marked out for the rollers. By thus drawing up the wool between the teeth, a portion of the wool will be left in them; the rollers then rise up rapidly in their oval course, and the wool is raised quite above the teeth; the rollers then move forwards to make another stroke, and during such advance, the rollers, being in continual motion, draw forwards the sliver of wool, and the end hangs down ready to be lashed on the teeth of the comb next time.

The motions of the small comb *K* must be next described. The whole machine receives its motion by means of a wheel or pulley *c*, *fig. 1*, upon the axis of the crank for the lasher *G*; *D* and *E* are the bevelled wheels by which the other crank is turned; at the extreme end of the axis *C* is a pinion, which turns a bevelled wheel *L*, and on the axis of this is a wheel turning two others *M M* of equal size; on the extremities of the axes of the wheels *M M* are two cranks *ll* of equal radii, which are both jointed to an iron bar *mm*, and both turning round together in the same direction, they cause the bar to move in a direction parallel to itself, and every part of the bar describes a circle equal to the radius of the cranks. The small comb *K* is fixed to this bar, and partakes of its motion, whereby the points of its teeth are carried horizontally into the wool contained in the teeth of the great comb, then rise upwards and draw through the fibres, in order to comb them.

In order to remove the little comb when it becomes filled with wool, it is attached to the bar *m* by means of a comb-holder or socket *L*, which has a groove at each end to receive the little comb, and it can be mounted or withdrawn at pleasure. This socket *L* is moveable upon a horizontal pin fixed at the end of the bar *m*, so that it can be turned with either end upwards; and as the little comb can be fixed at either end of the socket, a spare comb is placed in the upper groove of the socket, whilst the lower groove holds the comb which is in use; but when this becomes filled with wool, which it has gathered from the comb-table, the socket *L* is inverted by turning it half round upon its centre-pin, and by this means the fresh comb is brought down into use, and the other can be taken away to clear off the wool from it. There is a small bolt fixed to the pin on which the socket *L* turns, which can be shot into a notch when the socket is in a perpendicular position, and will then hold the socket fast from turning, and keep the comb in a proper position for its work. In this way, the little comb can be taken away and replaced by a fresh one as often as is necessary, without stopping the machine, for the small comb does not move very quick. The same boy who attends to change the combs, when necessary,

also sets up the wool in the great comb-teeth with a small scraper, so that the small comb will penetrate through it with more certainty and effect. The plane of the rows of teeth in the small comb is not horizontal, or parallel to the teeth of the combing-table, but inclined thereto, so that those teeth of the small comb which first come into action upon the wool do not penetrate deeply into it; but as the comb-table turns round, the wool advances beneath the small comb, and is operated upon those teeth which go deeper, and the last teeth of the comb go as deep as they can, not to touch the teeth of the comb-table.

The wool is now combed, and only remains to be drawn off in a continued sliver; this is done by the drawing-off rollers *N*, which are fluted iron rollers, placed horizontally over the comb-teeth, and nearly in the direction of a radius of the comb-table: they are supported in an iron frame, and are turned round by a pair of bevelled wheels from a vertical axis *P*. This axis extends the whole height of the machine, and is put in motion by means of a pair of bevelled wheels, and an oblique axis *Q*, which is turned by a bevelled wheel and pinion on the extreme end of the axis of the first crank-lasher.

The great comb receives its motion from the perpendicular axis *P*, which turns a large wheel *T* by a pinion on the lower end of it: on the upper end of the axis of this wheel is the pinion which works in the ring of teeth within side of the comb-table: in this way, a very slow motion is given to the comb-table. There are two pair of drawing-off rollers *N*, situated close together, and parallel to each other; the first pair are put in motion as we have described, and the back pair are turned by means of equal cog-wheels, so that they move with the same velocity.

The wool upon the comb-table is gathered in the hand, to form a sliver, and the end is introduced between the rollers, which continually draw off the wool as the comb-table turns round. After passing through both pairs of rollers, the sliver is conducted through a forked iron, then through a round wooden tube, and is at last delivered by two plain wooden rollers *R* into a tin can placed beneath to receive it. These rollers are also turned by bevelled wheels on the perpendicular axis *P*. The drawing-off rollers only take away the long wool, the fibres of which are long enough to reach to the rollers. The two rollers composing the front pair of drawing-off rollers are not placed immediately over each other, but the upper roller overhangs the lower one, so that the plane in which the axes of the upper and lower rollers are both situated is inclined at about an angle of 45 degrees to the plane of the comb-table: by this means, the wool is drawn off from the comb, at an angle of 45 degrees, to pass between the rollers.

The noils, *i. e.* the short wool and broken fibres, which will not reach the drawing-off rollers, remain in the teeth of the comb-table, and also as much of the long wool as is on the lower side of the comb, and these are called backings: both are taken off by a boy, who is seated for that purpose within the circle of the comb-table; he first draws off the backings from beneath the comb, and then, with one hand above the teeth, and the other below, he draws off the noils.

These two sorts of wool are handed to a boy on the outside of the machine, who puts them into separate boxes. The backings are filled on the small combs before they are put into the machine, and become somewhat combed by the action of the small comb: when the small combs are removed from the machine, the wool upon them is further combed by hand, and then drawn off from them in a continued sliver, by means of an additional piece of machinery, which is at the side of the machine.

WORSTED MANUFACTURE.

This combing-machine is found to break the fibre of the wool, and it increases the quantity of noil very much, unless the wool is previously combed once or twice by hand; and as it then becomes only a substitute for the second or third combing, it saves little or no expence. The advantage of the machine is found, in the great regularity and equality of the sliver which is produced by it, a circumstance of particular importance for fine spinning. In combing by hand when the sliver is drawn off, those fibres which the comb first takes hold of are longer than the others; then as the sliver continues to be drawn, shorter fibres are found in it, and the shortest are last of all. These are called the long and short ends of the sliver; the short end is always marked by twisting or rolling it up, in order that when the slivers are joined together into one for spinning, the long and short ends may be equally intermixed and dispersed throughout the whole length. In drawing off the wool from the combing-machine, the long and short fibres are intermixed and taken up together, so that the sliver is of very equal texture.

There have been several other attempts to make combing-machines which deserve notice, though they have not come into use.

Messrs. Wright and Hawksley had a patent in 1793 for a combing-machine; and Mr. Toplis of Cuckney had also a patent of the same date, which contains some good ideas. Mr. Hawksley, in 1797, had a patent for improvements on Cartwright's: the principal one was, to make the combing-table by the combination of a number of small combs, which could readily be applied to the table, or detached at pleasure. If this would allow the combs to be heated, as the inventor proposed, they would work much better.

Mr. Amatt had a patent in 1795, and Mr. Pearce in 1798: after this time, Mr. Cartwright's machines had received some improvements from Mr. Hawksley, and came into use; and we find less speculation on the subject.

Gilpin's Combing-Machine.—In 1811, Mr. George Gilpin of Sheffield perfected a very ingenious machine, which combed the raw wool in a most complete manner. We do not hear that this machine is yet come into use, although we have no doubt of its answering the purpose, having frequently examined it while at work: its only fault was a complication of parts, which might be easily removed.

The outline of this machine is taken from that of Mr. Coplis in 1793, but is very much improved and perfected. *Fig. 4. of Plate I. Worsted,* is a sketch of the principal parts. The machine works with eight combs at once, which are of rather larger size than the ordinary hand-combs, the rows of teeth being twenty inches long. These combs are fixed upon two reels or frames A, B, which revolve upon their axes by the power of the mill; our combs, D and E, are fixed upon each reel, and in such position that both ends of the comb-teeth, *viz.* the points and roots, are equally distant from the centre of the reel to which they are fixed; and the reels, with the combs fixed upon them, form two revolving wheels or frames. The combs D and E are so made, that they can be detached from the reels, or replaced and fixed fast in a moment, by the attendants; and they can, therefore, be heated in a stove, in the same manner as the hand-combs. The wool is also filled upon the combs by hand, and the combs and wool are heated in the usual manner before they are put into the machine, in order to comb the wool.

One of these reels A is simply turned upon its axis, but the other reel B has a curious compound motion given to it by the machinery: thus it revolves on its own axis; but the axis also advances to, and recedes from, the other reel with

a motion parallel to itself, which is repeated four times in every revolution. Whilst B advances towards A, it moves with only one-third of the velocity with which it returns from A. The advancing movement is of a limited and constant extent; but at the same time, there is a third movement which regulates this extent, so that at every succeeding stroke which the machine makes, the two reels will approach nearer together.

Suppose all the combs filled with wool, and mounted in their places upon the reels, the machine is then put in motion, and the two reels A and B turning round in opposite directions, their combs D and E meet each other; and by the compound movement of B, (*viz.* advancing slowly towards A, and turning round at the same time,) the combs D and E approach in such a manner, that the points of each comb penetrate the wool which is in the other comb, and this is reciprocal of both combs. When the teeth are thus entered into the wool, the moveable reel B retreats quickly from the other, and the teeth, by drawing through the wool, comb and separate its fibres.

The circular motion of both reels is not regular and equable, but is communicated by means of elliptical cog-wheels, which occasion the reels to move round very slowly, at the moment when the comb of the reel B is drawing out or combing the wool; but this motion being finished, the reels begin to turn round more rapidly, and at the same time the reel B approaches towards A with a slow movement, in order to present another pair of combs to each other, which meet; and each one penetrates the wool which is upon the other, and then the reel B draws out to comb it, in the manner before described.

In this way they continue to make successive strokes, until the wool is sufficiently combed: the machine is then stopped, and the combs taken off one by one, to be replaced by others, which are filled with fresh wool, and properly heated.

There is likewise another movement of the reel A, which we have not yet mentioned: the axis of that reel has a slow motion backwards and forwards, endways in the direction of its length, for a short distance. The intention of this is, that the same parts of the combs shall never come opposite to each other at two successive strokes.

It should be observed, that when the machine is first set to work, the combs at their point of meeting do not come within three or four inches of each other, and the points only penetrate amongst the longest fibres of the wool upon the combs; but at every stroke which is made, the combs advance nearer together, and take deeper into the wool, until, after a certain number of strokes are made, the combs approach as near as they can without touching. They continue to work in this manner for some time, and when the intended number of strokes is made, a bell rings as an indication that the machine should be stopped. This is done by drawing a lever, and in consequence the machine will stop itself in the exact position for changing one of the combs on each reel. These are removed, and others ready filled with wool and heated are put on in their places, which being done on both reels at the same time by two persons, is only the work of a moment. The machine is then put in motion again, but by the machinery it will stop itself again at the required position for changing the next pair of combs; it is then put forwards, and so on, until all the eight combs are changed.

The combs which are removed from the machine are put into the stove to heat for a few moments, and then the wool is drawn off from them by a separate machine. The head of the comb is here placed in a perpendicular groove, so that its teeth stand horizontal; and a piece

of metal, which is fixed to the head of the comb, and projects therefrom like a tooth, enters into the spiral groove of a screw, which stands in a perpendicular position, and is continually turned round by the machinery. By this means, the comb is regularly and slowly let down in the groove, from top to bottom. A pair of fluted rollers is placed horizontally, and parallel to the teeth of the comb, in such a position that the comb, in descending, will pass with its teeth at a proper distance from them, to draw off the wool in a sliver. After passing through these fluted rollers, the sliver is conducted through a perpendicular revolving tube, which gives a roundness to it, the same as it would acquire by being rolled between the hands, and then it is conducted between a pair of plain rollers, which deliver it into a tin can placed before the machine.

A wooden roller is placed above the fluted rollers, with eight pieces of board projecting from it in the direction of radii. When the roller turns round, these boards act to stroke the wool upon the comb, and raise it into a proper situation to be drawn off by the fluted rollers.

The combs are prepared for drawing off the wool, by heating them as before mentioned, and by sliding the wool from the roots of the teeth half way towards their points. In this state, the combs are carried one by one to the drawing-off machine, and the head of one comb is put into the top of the perpendicular groove: it will be prevented from falling down in the groove by the projecting tooth, which enters the spiral groove of the perpendicular screw. The wool is gathered up and introduced between the fluted rollers; the machine is then put in motion, and by means of the screw the comb is gradually lowered down, and the wool is drawn off from it in a sliver, which is rolled up into a compact form by the revolving tube, through which it passes, and is delivered into the can by the plain rollers.

The attendant holds another comb ready to follow the first, and when the first has descended to a certain point, he slips the next comb into the perpendicular groove, so that it rests upon the former, and the wool upon the two combs joins as it were in one. The stroker, when they pass before it, lays the fibres all one way, and the wool is drawn off by the rollers in a continued sliver, which does not present the slightest appearance of joinings. Another comb is then put in, and the wool joins to the former, and so on. The backings, or wool at the back of the comb, are drawn off by the boy stationed behind the machine; and the combs, as they come through below, are received by boys, who afterwards take away the noil or short wool which remains in the teeth, and then put the combs back into the stove to heat them, ready to be filled again, in order to proceed with another combing. When the wool of all the eight combs is drawn off, the motion of the drawing-off machine is stopped at the moment when the eighth or last comb has descended half way through its course. In this state, the machine waits till another combing is finished, and then the succeeding comb being placed on the top of that one which continues in the machine, the continuity of the sliver will be preserved.

The inventor of this machine states in his specification, that for common work the wool only requires to be operated upon once by the combing-machine; and in that case, the machine must be adapted to make twenty-four strokes of each pair of combs before the bell rings. For medium work, such as would require to be combed twice over, in the usual manner of hand-combing, it must be combed twice over by the machine: thus, after having been combed once in the manner before described, the sliver of wool is broken up into handfuls, and filled on the combs again by hand as

before, and combed over again in a similar manner; but the combs are less heated for the second time of combing. By changing a wheel, the machine should be adapted to make only fourteen or sixteen strokes before it stops, when it is intended to comb twice over. The wool intended for the finest spinning should be combed three times over, and the machine should be set to make fourteen or sixteen strokes of each pair of combs.

The machine has also two different movements for the drawing out of the moveable comb-reel: in one, the motion is over a space of ten inches, and is adapted to comb such wool as is six or eight inches length of staple, and is called wether wool; but by a slight alteration, the excursion of the moveable reel can be increased to thirteen inches, and is then adapted to comb hey wool, or wool which is from eight to eleven inches length of staple.

Mr. Gilpin's machine has the advantages of heating the combs and of filling them by hand, both of which are essential to any machine which is proposed to comb the raw wool. The filling is an operation which requires discretion, if it is expected that the long fibres shall be preserved without breaking. The person who fills the wool on the teeth takes a greater or less lock of wool in his hand, according to the condition of it, and the degree of entanglement: also in drawing it between the comb-teeth, the force is proportioned to what the wool will bear. Mr. Gilpin's specification states, that under certain circumstances, when the wool will not wash well, but remains taggy, it is advisable to fill it upon the combs, and slip it off; then fill it again, preparatory for the machine. As the object of this first filling is chiefly to warm the wool, the end may be in part attained by laying the wool upon the top of the stove for a few minutes before it is filled.

Planking.—Let us suppose that the wool is combed either by the hand, or by the machine, and we will proceed to explain the means of preparing it into a thread. The combing-machines reduce the wool into a continued sliver, which is ready for the drawing-frame; but the short slivers produced by the hand-combing must be first joined together by what is called planking. These slivers are rolled up by the combers, ten or twelve together, in balls called tops, each of which weighs half a pound: at the spinning-mill these are unrolled, and the slivers are laid on a long plank or trough, with the ends lapping over, in order to splice the long end of one sliver into the short end of another. The distinction of the two ends of the sliver has been before explained; the long end being that which was first drawn off from the comb, and contains the longest fibres of the wool; the short end is that which came last from the comb, and contains the short fibres. The wool-comber lays all the slivers of each ball the same way, and marks the long end of each by twitting up the end of the sliver. It is a curious circumstance, that when a top or ball of slivers is unrolled and stretched out straight, they will not separate from each other without tearing and breaking, if the separation is begun at the short ends, but if they are first parted at the long ends they will readily separate.

Breaking-Frame.—Here the slivers are planked or spliced together, the long end of one to the short end of another; they are immediately drawn out and extended by the rollers of the breaking-frame. A sketch of this machine is given in *Plate II. fig. 5*; it consists of four pairs of rollers, A, B, C, D. The first pair A receives the wool from the inclined trough E, which is the planking-table. The slivers are unrolled, parted, and hung loosely over a pin, in reach of the attendant, who takes a sliver and lays it flat in the trough, and the end is presented to the rollers A, which being in motion

WORSTED MANUFACTURE.

motion will draw the wool in; the sliver is then conducted through the other rollers, as shewn in the figure: when the sliver has passed half through, the end of another sliver is placed upon the middle of the first, and they pass through together; when this second is passed half through, the end of a third is applied upon the middle of it, and in this way the short slivers produced by the combing are joined into one regular and even sliver.

The lower roller C receives its motion from the mill, by means of a pulley upon the end of its axis, and an endless strap. The roller which is immediately over it is borne down by a heavy weight *e*, suspended from hooks, which pass over the pivots of the upper roller. The fourth pair of rollers D moves with the same velocity as C, being turned by means of a small wheel upon the end of the axis of the roller C, which turns a wheel of the same size upon the axis of the roller D, by means of an intermediate wheel *d*, which makes both rollers turn the same way round. The first and second pairs of rollers, A and B, move only one-third as quick as C and D, in order to draw out the sliver between B and C to three times the length it was when put on the planking-table. The slow motion of the rollers A is given by a large wheel *a*, fixed upon the axis of the roller A, and turned by the intermediate cog-wheels *b*, *c*, and *d*; the latter communicates between the rollers C and D. The pinions on the rollers C and D being only one-third the size of the wheel *a*, C and D turn three times as fast as A, for *b*, *c*, and *d*, are only intermediate wheels. The rollers B turn at the same rate as A. The upper roller *c* is loaded with a heavy weight, similar to the rollers A; but the other rollers, B and D, are no farther loaded than the weight of the rollers.

The two pairs of rollers A B and C D are mounted in separate frames, and that frame which contains the third and fourth pairs, C D, slides upon the cast-iron frame F, which supports the machine, in order to increase or diminish the distance between the rollers B and C. There is a screw *f*, by which the frame of the rollers is moved, so as to adjust the machine according to the length of the fibre of the wool. The space between B and C should be rather more than the length of the fibres of the wool. The intermediate wheels *b* and *c* are supported upon pieces of iron, which are moveable on centres: the centre for the piece which supports the wheel *b* is concentric with the axis of the roller A; and the supporting piece for the wheel *c* is fitted on the centre of the wheel *d*. By moving these pieces, the intermediate wheels *b* and *c* can be always kept in contact, although the distance between the rollers is varied at times. By means of this breaking-frame, the perpetual sliver which is made up by planking the slivers together is equalized, and drawn out three times in length, and delivered into the can G.

Drawing-Frame.—Three of these cans are removed to the drawing-frame, which is similar to the breaking-frame, except that there is no planking-table E. There are five sets of rollers, all fixed upon one common frame F, the breaking-frame which we have described being the first. As fast as the sliver comes through one set of rollers, it is received into a can, and then three of these cans are put together, and passed again through another set of rollers. In the whole, the wool must pass through the breaker and four drawing-frames before the roving is begun. The draught being usually four times at each operation of drawing, and three times in the breaking, the whole will be $3 \times 4 \times 4 \times 4 \times 4 = 768$; but to suit different sorts of wool, the three last drawing-frames are capable of making a greater draught, even to five times, by changing

the pinions; accordingly the draught will be $3 \times 4 \times 5 \times 5 \times 5 = 1500$ times.

The size of the sliver is diminished by these repeated drawings, because only three slivers are put together, and they are drawn out four times; so that in the whole, the sliver is reduced to a fourth or a ninth of its original bulk.

The breaking-frame and drawing-frame, which are used when the slivers are prepared by the combing-machines, are differently constructed; they have no planking-table, but receive three of the perpetual slivers of the combing-machine from as many tin cans, and draws them out from ten to twelve times. In this case, all the four rollers contribute to the operation of drawing: thus the second rollers B move $2\frac{2}{3}$ times as fast as the rollers A; the third rollers C move 8 times as fast as A; and the fourth rollers E move $10\frac{1}{3}$ times as fast as A. In this case, the motion is given to the different rollers by means of bevelled wheels, and a horizontal axis, which extends across the ends of all the four rollers, to communicate motion from one pair of rollers to another.

There are three of these systems of rollers, which are all mounted on the same frame; and the first one, through which the wool passes, is called the breaking-frame, but it does not differ from the others, which are called drawing-frames. The slivers which have passed through one system of rollers are collected four or five together, and put through the drawing-rollers. In all, the slivers pass through three drawings, and the whole extension is seldom less than 1000 times, and for some kinds of wool much greater.

After the drawing of the slivers is finished, a pound weight is taken, and is measured by means of a cylinder, in order to ascertain if the drawing has been properly conducted; if the sliver does not prove of the length proposed, according to the size of worsted which is intended to be spun, the pinions of some of the drawing-frames are changed, to make the draught more or less, until it is found by experiment that one pound of the sliver measures the required length.

Roving-Frame.—This is provided with rollers the same as the drawing-frames: it takes in one or two slivers together, and draws them out four times. By this extension, the sliver becomes so small, that it would break with the slightest force, and it is therefore necessary to give some twist; this is done by a spindle and flyer. (See *fig. 6.*) A B are the two pairs of rollers, between which the sliver is passed; the first rollers A turn round slowly, but the others B revolve four times as quick, to draw the sliver to four times its original length; and as fast as it issues from the roller, it is twisted by the motion of the spindle C, and wound up upon the bobbin *a*. The spindle C is put in motion by a whip-cord band, which passes round the pulley *c*, and also round the wheel D. This wheel is fixed on a vertical axis *e*, which has a pinion on the upper end, to give motion to the lower roller B, by means of a bevelled wheel upon the end of its axis. The opposite end of the axis has also a bevelled pinion upon it, to give motion to a bevelled wheel fixed upon an horizontal axis, which carries another bevelled pinion, to give motion to a bevelled wheel fixed upon the end of the axis of the back rollers A. The sizes of these wheels and pinions are so proportioned, that the back rollers A turn only once to every four turns of the front rollers B, as before mentioned.

The back rollers are capable of being set at a greater or less distance from the front rollers, according to the length of the fibres of the wool, and in all cases the distance should be rather more than the length of the fibres, but not a great deal.

The spindle is supported on its point, and sustained by a collar at the middle of its length. Upon the top of the spindle, the flyer *e* is screwed; it has two branches, which turn downward, and one of them has an eye at the lower end, through which the roving is conducted, in order to lay it upon the bobbin *a*. This bobbin is fitted loosely upon the upper part of the spindle, and rests with its weight upon a piece of wood projecting from the bobbin-rail *f*. The rail is made to rise and fall continually with a slow motion, so as to present every part of the bobbin in succession to the eye of the flyer, and thereby wind the roving upon every part of the length of the bobbin. The bobbin is not fixed upon the spindle, but is fitted loosely thereupon; and by resting upon the piece of wood which is fixed to the bobbin-rail, there is so much friction and resistance to the motion of the bobbin, that it gathers up the roving by winding it round itself as fast as the rollers give it out. The twist given to the roving is just enough to make it hang together, and one turn in each inch is usually enough. Some roving-frames are made with four pairs of rollers, and draw ten or twelve times; and in this way, it is not necessary for the sliver to pass so frequently through the drawing-frame.

Spinning-Frame.—This is so much like the roving-frame, that a short description will be sufficient. The spindles are more delicate, and there are three pairs of rollers instead of two; the bobbins which are taken off from the spindles of the roving-frame, when they are quite full, are stuck upon wires at *L* (*fig. 7.*), and the roving which proceeds from them is conducted between the rollers. The back pair *A* turns round slowly; the middle pair turns about twice for once of the back rollers; and the front pair *B* makes from twelve to seventeen turns for one turn of the back rollers *B*, according to the pinions which are employed, and these can be changed according to the degree of extension which is required.

The spindles must revolve very quickly in the spinning-frame, in order to give the requisite degree of twist to the worsted. The hardest twisted worsted is called tammy-warp, and when the size of this worsted is such as to be twenty or twenty-four hanks to the pound weight, the twist is about ten turns in each inch of length. The least twist is given to the worsted for fine hosiery, which is from eighteen to twenty-four hanks to the pound. The twist is from five to six turns *per* inch. The degree of twist is regulated by the size of the whirls or pulleys upon the spindle, and by the wheel-work, which communicates the motion to the front rollers from the band-wheel, which turns the spindles.

It is needless to enter more minutely into the description of the spinning machinery for worsted, because the construction is very similar to the water-frame for spinning cotton, invented by sir Richard Arkwright, and which is fully described in our article *Manufacture of COTTON*. The differences between the two are chiefly in the distance between the rollers, which in the worsted-frame is capable of being increased or diminished at pleasure, according to the length of the fibres of the wool, and the draught or extension of the roving is far greater than in the cotton.

Reeling.—The bobbins of the spinning-frame are placed in a row upon wires before a long horizontal reel, and the threads from 20 bobbins are wound off together. The reel is exactly a yard in circumference, and when it has wound off 80 turns, it rings a bell; the motion of the reel is then stopped, and a thread is passed round the 80 turns or folds which each thread has made: the reeling is then continued till another 80 yards is wound off, which is also separated by interweaving the same thread; each of these

separate parcels is called a ley, and when seven such leys are reeled, it is called a hank, which contains 560 yards. When this quantity is reeled off, the ends of the binding thread are tied together, to bind each hank fast, and one of the rails of the reel is struck to loosen the hanks, and they are drawn off at the end of the reel. These hanks are next hung upon a hook, and twisted up hard by a stick, then doubled, and the two parts twisted together, to make a firm bundle. In this state, the hanks are weighed by a small index-machine, which denotes what number of the hanks will weigh a pound, and they are sorted accordingly into different parcels. It is by this means that the number of the worsted is ascertained as the denomination for its fineness: thus No. 24. means that 24 hanks, each containing 560 yards, will weigh a pound, and so on.

This denomination is different from that used for cotton, because the hank of cotton contains 840 yards instead of 560; but in some places, the worsted hank is made of the same length as the cotton.

To pack up the worsted for market, the proper number of hanks are collected to make a pound, according to the number which has been ascertained; these are weighed as a proof of the correctness of the sorting, then tied up in bundles of one pound each, and four of these bundles are again tied together. Then 60 such bundles are packed up in a sheet, making a bale of 240 pounds, ready for market.

From this account of the processes of worsted spinning, it will be seen that they are very similar to those of cotton-spinning, after the first preparation of the wool by combing instead of carding.

Worsted-Cord, in *Sheep-Farming*, is a sort of cord which is sometimes used for tying round the necks of sheep affected with the scab, after it has been well smeared over with the common mercurial ointment of the shops, in order to cure them of that disease. See *SCAB*.

WORT, in the *Materia Medica*, is the sweet infusion of malt; first proposed by Dr. Macbride as a dietetic article to scorbutic persons, from an apprehension that it would ferment in their bowels, and give out its fixed air, by the antiseptic powers of which the strong tendency to putrefaction in this disease might be corrected. It was some time before a fair trial of this proposed remedy could be obtained, and different reports were made concerning it. In 1762, the lords of the admiralty gave orders to have the wort tried in the naval hospitals at Portsmouth and Plymouth; but the murmurs of the patients, on account of restrictions that were necessary for determining its efficacy, put a stop to the farther exhibition of it; and indeed Dr. Huxham, in 1764, informed the ingenious and benevolent proposer of this remedy, that it had been tried with very bad effects. But Dr. Macbride assures us, on the testimony of a gentleman who made use of the wort, that it may be taken for a length of time, to the quantity of a quart in the day, without producing any ill effect whatever; and he refers to Van Swieten's Commentary, vol. iv. p. 673. where we learn, that the baron's lady, when a nurse, used regularly to drink a pint of it every night going to bed, in order to increase her milk.

After the failure of success in the naval hospitals, orders were issued to have the wort administered on ship-board, where no temptations of fresh vegetables would offer to make the men uneasy. But a considerable time elapsed, before any reports were made either of its good or bad effects. Dr. Macbride, however, persisted in recommending

ing it, and lived to publish several cases, in a postscript to the second edition of his work, in 1767, from which it appears, that scorbutic complaints of the most dangerous kind have actually been cured at sea by the use of wort. Its general effects were, to keep the patients open, and to prove highly nutritious and strengthening; it sometimes purged too much; but this effect was easily obviated by the tinctura thebaica. Other unquestionable cases of its success in this disease are to be seen in the London Med. Obs. and Inq. vol. v. p. 61. See also SCURVY.

The use of wort has hence been adopted in other cases, where a strong putrid disposition in the fluids appeared to prevail, as in cancerous and phagædenic ulcers; and instances are published of its remarkable good effects in these cases. See London Med. Obs. and Inq. vol. iv. p. 367, &c. Priestley on Air, vol. 3. Appendix.

As the efficacy of the malt infusion depends upon its producing changes in the whole mass of fluids, it is obvious that it must be taken in large quantities for a considerable length of time, and rather as an article of diet than medicine. The quantity of one to four pints has generally been directed. See SCURVY.

WORT, *Improved Machine for stirring Malt in making of, in Rural Economy*, a contrivance for this purpose in brewing and distilling, suited to vats of this sort, which are employed in forming the wort or wash. There are many modes of stirring malt in the vats or tubs for mashing in, employed in different places and instances; but they are in most cases either expensive, or inadequate to the purposes as well as the powers which are made use of in the work. Among the former may be ranked the admirably well-contrived machine that is in use by Jellet and Co. at Dollhill, in Somersetshire, which is on a planetary system, and answers the intention very effectually; but its great cost renders it liable to objection in many cases. The well-known contrivance of a male screw standing upright in the centre of the vat, on which a bar works by means of a female screw operating on the male standard one, and thus causing the spikes with which the different wings of the bar are armed to stir the malt as the spiral motion proceeds, is certainly simple, neat, and cheap; but as it requires two men, one at each end, and makes but little change of locality among the malt-grain, much cannot be urged in favour of its efficiency for this use. The instrument known by the name of the hedge-hog, which is in use in some breweries, is a dreadful-looking machine, that would seem intended to divide some very tough or viscid substance rather than to stir malt in this intention. It consists of a roller about two feet in diameter, and six or seven in length, made of iron skeleton work; the longitudinal bars are bound with rings or hoops, furnished with spiky rims, to keep in due bounds a sort of chain-work, armed also with spikes, which chains revolve upon the rings as the frame rolls round, urged by the power of horses, and thus not only tears a passage through the contents of the mashing-vat, but keeps raking them up, carrying a considerable portion with the spiky chain quite over the wheel, and exposing the malt perpetually to the influence and action of the air; a practice invariably disapproved of by all good brewers. In this case, there are expence, labour, friction, &c. all crowded into one form, without any material advantage.

A plan has, however, been lately suggested for stirring malt while in the mashing-vat by a machine or contrivance wrought by the power of horses, or in other ways, which is nearly without friction, and divested of the intervention of any secondary action that may be troublesome or expensive. It is very simple; and one vat of this sort may be stirred

by a very trifling power; but as in large breweries and distilleries from malt a number of mashing-vats are mostly requisite, which generally require to be stirred in succession, an arrangement is given for facilitating and bringing the operations of five vats, one in the middle and four around it, into a narrow or small compass, and under the action of one power; which not only affords much convenience, but occasions the expence and the labour to be greatly lessened; consequently it may be useful in large as well as small establishments of this nature.

In this plan, the central circular vat for this purpose is raised sufficiently to admit the necessary gear and other matters for a horse-walk underneath it. The upright axle passes through the floor, and through the centre of the vat, proceeding up to a beam in which it moves in a metal bush, as it does also below, where it rests on a step. It does not, however, touch either the floor or the vat; but at the distance of a few inches it is surrounded by a cylinder, forming part of the vat, which prevents its contents from passing through the aperture in the floor. This cylinder corresponds in height with the exterior edge of the vat, and is firmly closed at the bottom, where, as well as at the outer part, it is rounded off, so as to be the more easily drained and cleaned.

As it is requisite at times to move the malt in the other vats, while the central one is at rest, there arises a necessity for constructing the wings of the stirring-frame in the latter in such a manner as may liberate them, leaving them inactive, while the axle proceeds in its ordinary revolutions.

The stirring-frame is made of iron; it has four wings standing at right angles, and they all join to an iron collar which surrounds the axle at some distance, that is, leaving about an inch intermediately all around. When the stirring-frame is to move with the axle, it is fastened to it by two iron pins, with long handles, so as to enable the workmen to affix them in their proper sockets, without going into the vat. These pins pass through the collar into the axle, thereby causing the stirring-frame to move round in the vat, as the axle is moved round by the horse, or other power.

As the stirring-frame in the centre vat cannot be connected all the way down its depth with the axle, on account of the cylinder, and as it would be liable to swag, if depending entirely on its junction with the collar, oblique stays are indispensable; they are carried out about two-thirds of the length of the frame, where they are rivetted: their upper ends are secured to another collar, surrounding the axle above.

Each wing of the frame consists of two iron bars, one at the top, and one at the bottom; between the bars are three fixed upright valves made of thin sheet-iron, and standing at angles of forty-five degrees; and they are fastened above and below into the horizontal iron bars, so as to be perfectly strong and steady in their positions. The valves do not, however, all stand the same way: the internal ones all point inwards, the outward ones all point outwards, and the middle ones alternately inwards and outwards.

Thus far wholly relates to the central vat, which may be surrounded by four others of less capacity, in which there will be found the differences noticed below: 1. That the bottoms not being perforated no cylinders are required. 2. That the axles for their respective frames rest on steps at their bottoms, in which iron gudgeons move in iron bushes. 3. That the frames all connect with the axles for the whole of their depth. And 4. That no stays or collars are wanted in them.

On the main axle are four drums of about one-fourth the diameter of the centre vat ; they are each about one foot in thickness, and deeply grooved all around, like the sheave of a pulley, for the purpose of receiving a band. An interval of about six inches is left between them, in the intention of receiving the band respectively, so that the corresponding drums on the axles in the other vats may be left at rest whenever those vats are not at work. Thus the four drums which are firmly fixed to the main axle, and revolve with it, turn the four drums fixed to the axles in the four vats respectively. But as the four drums on the main axle are all of different heights from the surface of the vat, the several drums on the axles in the other vats must be respectively of corresponding heights with those that act upon them on the main axle. An idea of the manner in which the bands extend to the four vats may be formed by observing that in order to produce greater constriction, and consequently greater power, they all form a figure of 8 in their progress ; thereby occasioning the four furrouring vats to be stirred by a counter motion : that is, the frames will revolve the opposite way to that in the central vat. The drum on each of the lesser vats should, however, be of the same size as that on the central axis from which it receives its motion, whereby the whole will move at the same rate, and the malt be equally stirred.

The intervals between the different vats will allow ample access to the works, and admit besides of standards, &c. for the support of the flooring above, there being no part of the machinery that in the least interferes with those spaces ; and the bands being completely out of the passage of all work, they can be easily shifted off and on to the central drum by means of a pole with an iron at its end, formed so as to embrace and direct them into the grooves.

On the whole it is supposed, that the plan here laid down may be safely asserted to be cheap, simple, and effectual ; and that it would not probably be easy to find any machinery for this use less complex, and in which the power is so immediately applicable to the object. For though it might be objectionable in work requiring perfect regularity, and an unvaried equable motion, without which the operations would be ill performed, and the machinery itself be liable to great injury, and to be perpetually out of order, yet in the business of merely stirring the malt in a mashing-vat in the making of wort or wash, inequality of motion can never produce any bad effect.

The driving power in these cases should move rather slowly, and when of the animal kind, it may be increased without the addition of more strength, merely by extending the length of the lever, and causing the animal by such means to describe a larger circle ; but which may not, however, be always convenient for want of perpendicular support for the flooring above. On most occasions, the mashing-vats in making wort or wash may, however, be computed not to exceed twelve feet in diameter, in which cases the horse-walks need not be more than twenty feet over, equal to about twenty yards in circumference ; and in this case, supposing the horse to move at the rate of two miles in the hour, he would go round eighty-eight times in the course of that time, and cause the malt to be stirred nearly three times in the space of every two minutes ; but if the lever were longer, the motion within the vats would be slower in proportion.

WORTH, in *Geography*, a town of Bavaria ; 12 miles E. of Ratisbon.—Also, a town of the principality of Hesse Darmstadt ; 20 miles E.S.E. of Darmstadt.

WORTH Barrow Bay, a bay of the English Channel, on

the fourth coast of the county of Dorset ; 11 miles E. of Weymouth.

WORTHIEST of Blood, in *Law*, an expression denoting the preference given in descents to sons before daughters.

WORTHING, in *Geography*, a fashionable and much-frequented watering-place in the parish of Broadwater, and county of Suffex, England, is situated on the sea-coast, 11 miles W. from Brightelmstone, $9\frac{1}{2}$ E.S.E. from Arundel, and 58 S. by W. from London. Formerly an obscure fishing-village, Worthing is much indebted for its present improvement to its situation on a very extensive stretch of fine level sandy beach, peculiarly convenient for bathing, and to the range of chalk-hills behind it called the South Downs, affording at once shelter to the town and sands, and space for exercise to the invalid. The town extends northward from the shore, but some new buildings are situated near the beach, and are adapted to the reception of families of the first rank. The Steyne, a range of handsome houses, and the parallel row called Warwick-buildings, form the E. and W. sides of a square, open to the sea on the S. and to the Downs on the N. A quarter of a mile from the beach is a neat chapel, erected by subscription in 1812. Worthing has a theatre, libraries, bathing-machines, and warm baths, and is thus amply provided for the use and amusement of visitors. Warwick-house is not only the most distinguished mansion in Worthing, but for its extent and appearance entitled to a high rank among the noble mansions of the kingdom. It was erected by the earl of Warwick, while proprietor of the manor of Broadwater ; but no longer belonging to that family, it is usually occupied by some persons of distinction in the bathing-season. Broadwater village is half a mile from Worthing ; it was the chief place of the barony of Camois, in the time of Edward I. The parish also comprehends Offington, the ancient but now much-altered seat of the lords de la Warr. The church of Broadwater is constructed on the cathedral plan, with a mixture of the circular and early-pointed styles of architecture. The population of Worthing fluctuates according to the season of the year ; but that of the whole parish of Broadwater, in 1811, was 2692 persons, and the houses were 629.—*Beauties of England and Wales, Suffex ;* By F. Shoberl, 8vo. London, 1813.

WORTHINGTON, a post-town of Massachusetts, in the county of Hampshire, containing 1391 inhabitants ; 19 miles N.W. of Northampton.

WORTLEY, a township in the parish of Tankersley, and county of York, England. According to the population report of 1811, it contained 173 houses, and 925 inhabitants, most of whom were employed in agriculture.

WORTON CREEK, a river of Maryland, which runs into the Chesapeake, N. lat. $39^{\circ} 20'$. W. long. $76^{\circ} 16'$.

WORTOWA, a town of Bohemia, in the circle of Chrudim ; 14 miles S. of Chrudim.

WORUMBANG, a town of Africa, in Mandingo. N. lat. $12^{\circ} 40'$. W. long. $6^{\circ} 55'$.

WOSCHNICK, or **WOZNICKI**, a town of Silesia, in the principality of Oppeln ; 14 miles N.N.E. of Beuthen.

WOSITZ, a town of Pomerelia ; 10 miles S.E. of Dantzic.

WOSSBERK. See **WEISENBERG**.

WOSTERZEDECK, a town of Bohemia, in the circle of Kaurzim ; 12 miles S.W. of Kaurzim.

WOSTOCK, a town of Brandenburg, in the Middle Mark ; 11 miles S.S.E. of Berlin.

WOSTROW, a town of Bohemia, in the circle of Czaflau ; 12 miles S.W. of Czaflau.

WOTCHAT,

WOTCHAT, in *Agriculture and Rural Economy*, a term provincially applied in some districts to an orchard.

WOTRALLY, in *Geography*, a town of Hindoostan, in Myfore; 8 miles N. of Allumbaddy.

WOTROW. See OSTRITZ.

WOTTON, Sir HENRY, in *Biography*, was born at Boughton-hall, in Kent, in 1568, and in 1584 entered of New college, Oxford, from which he removed to Queen's college. During his residence in the university, he applied with diligence to the study of logic and philosophy, of polite literature and civil law, and at this time composed a tragedy, which gained the applause of his fellow-collegians. Upon the death of his father in 1589, he availed himself of the small patrimony that was left to him in travelling through France, Italy, Germany, and the Low Countries, in order to improve his acquaintance with men and manners in these several countries. On his return in 1596, he was appointed secretary to the earl of Essex; and when this nobleman was apprehended on a charge of high treason, he consulted his own safety by quitting the kingdom. As he fixed his residence chiefly at Florence, he employed himself in composing a treatise, which was published after his death in 1657, under the title of "The State of Christendom; or, a most exact and curious Discovery of many secret Passages and hidden Mysteries of the Times." When a plot was detected by the grand-duke of Tuscany for taking away the life of James, king of Scotland, Wotton was engaged to communicate intelligence of it to the king. Having fulfilled this mission, he returned to Florence; and when James came to the crown, he recompensed his service by conferring upon him the honour of knighthood. In 1604 he was appointed ambassador in ordinary to Venice, where he acquired such reputation that several young gentlemen of rank attended him for improvement. In his way through Augsburg, he drew up the following humorous definition of an ambassador:—"Legatus est vir bonus peregre missus ad mentiendum reipublicæ causa;" *i. e.* an ambassador is a good man, sent abroad to lie for the service of his country. This sentence was afterwards alleged as a maxim avowed by the religion professed by the king of England; and it so far excited the displeasure of James, that Wotton, after his return, remained for five years unemployed. An apology, however, regained the royal favour, and he was sent on an embassy first to the United Provinces, and afterwards in 1615 to Venice. After three years' residence he returned with the hope of succeeding to the office of secretary Winwood, but he was otherwise employed in various foreign embassies, from the last of which to Venice he did not return till after the death of James, when he was appointed, as a recompence for his services, to the provostship of Eton college in 1624. Soon after his settlement in this situation, he published his "Elements of Architecture." But as the statutes of the college required his assuming the clerical character, he took deacon's orders, without undertaking what he considered as too serious a charge, the cure of souls. In his domestic entertainments he maintained the reputation of hospitality, and in his connection with the seminary over which he presided, he was a liberal encourager of genius and application. For the amusement of advanced life he had contemplated a life of Luther, with the history of the Reformation; but Charles I. persuaded him to undertake a history of England, in which, however, he made little progress. Having large demands on government for money advanced in foreign services, his circumstances were embarrassed, and he frequently solicited his majesty to grant him new preferment. But death was the only termination

of his wants and wishes; and this happened in December 1639, in the 72d year of his age. His remains were interred in the chapel of Eton college, and the following epitaph was inscribed on the stone that covered them by his own order: "Hic jacet hujus sententiæ primus autor, *Disputandi Pruritus Ecclesiarum Scabies*. Nomen alias quære." His accomplishments and literary acquisitions were very distinguished; and they are hyperbolically stated in Cowley's elegy, when he speaks of him as one

"Who had so many languages in store,
That only fame shall speak of him in more."

Business occupied so much of his time, that he had little leisure for writing. After his death were published his "Reliquiæ Wottonianæ;" and they have often been reprinted. Of his poems, there is one entitled "A Hymn to my God in a Night of my late Sickness," which has been highly extolled. *Biog. Brit.*

WOTTON, WILLIAM, a learned clergyman, was born in 1666, and under the tuition of his father, who was also a clergyman, he became a perfect phenomenon as to the knowledge of languages; for at the age of five years he could read the Latin, Greek, and Hebrew languages almost as well as English. Accordingly he was entered of Catharine-hall, Cambridge, some months before he was ten years of age: at twelve years and five months he took the degree of B.A., some time before which he had been celebrated in a copy of verses by Dr. Dupont, not only for his acquaintance with the learned languages, including Arabic, Syriac, and Chaldee, but his knowledge of geography, logic, philosophy, mathematics, and chronology. He commenced B.D. in 1691, and being chaplain to the earl of Nottingham, this nobleman presented him in 1693 to the rectory of Middleton-Keynes, in Buckinghamshire. His first work appeared in 1694, and was entitled "Reflections upon Ancient and Modern Learning." A second edition was published in 1697, and to this was annexed Dr. Bentley's Dissertation upon Phalaris, which involved Wotton in controversy, and subjected him to the sarcasm of Swift's *Battle of Books*. Wotton defended his own book against the objections of Sir W. Temple and others, and some observations in the *Tale of a Tub*, in the third edition in 1705. In 1701 he published "The History of Rome, from the Death of Antoninus Pius to the Death of Severus Alexander," 8vo. undertaken at the request of bishop Burnet, for the use of his pupil the duke of Gloucester; and recommended by Leibnitz to George II. when electoral prince. In 1706 he attacked "Tindal's Rights of the Christian Church," and in 1707 archbishop Tenison conferred upon him the degree of D.D. Notwithstanding his talents and learning, his life was irregular, and of course his circumstances embarrassed, so that in 1714 he was obliged to retire into South Wales, where he employed himself in writing. He also acquired the Welsh language, and was able to preach in it. Dr. Wotton, says one of his biographers, was one of those scholars, whose early proficiency, being chiefly the result of an extraordinary memory, was not followed by mature products corresponding to the expectations they excited. He died at the age of 60, in the year 1726. *Nichols's Lit. Anecd. Gen. Biog.*

WOTTON-under-Edge, in *Geography*, a large and populous market-town in the upper division of the hundred of Berkeley, Gloucestershire, England, is situated at the base of a ridge of woody hills (whence its name is evidently derived), at the distance of 19 miles S.S.W. from Gloucester, and 108 miles W. by S. from London. It is a borough by prescription, though it sends no members to parliament. In the

the reign of king John it was nearly destroyed by fire, and a place called the Brands is supposed to mark its ancient site. The present town consists of several streets, and stands on nearly sixty acres of ground; the buildings in general are good, and some, belonging to families of property, are modern and elegant. The government of the town is vested in a mayor and twelve aldermen. In the year 1252, Maurice, lord Berkeley, an ancestor of the present earl of Berkeley, who now holds the manor, obtained a grant of a weekly market on Fridays, and an annual fair, both of which are still held. The church is a spacious, handsome fabric, and contains numerous monuments and sepulchral memorials. Here is a free-school, erected in 1385, by Catherine, relict of Thomas, lord Berkeley: also an alms-house for six poor men and six women, built and endowed in 1632, by Hugh Perry, alderman of London, at the charge of 1000*l.*: a like sum was given by sir Jonathan Dawes, sheriff of London, for the relief of the poor. In the population return of the year 1811, the houses in this town were enumerated as 217, the inhabitants as 1527; the latter are chiefly employed in the clothing manufacture, which is carried on to a considerable extent in the town and its vicinity: one factory only, called New Mill, employs under its roof about 200 men, women, and children. Spanish wool alone is manufactured at this place, and is employed for the weaving of broad-cloth and kerseymere.—Rudge's History of Gloucestershire, 2 vols. 8vo. 1803. Beauties of England and Wales, vol. v. Gloucestershire, by J. Britton and E. W. Brayley, 1804.

WOTYECROW, a town of Poland, in the palatinate of Lublin; 12 miles W.S.W. of Lublin.

WOTZLERSDORF, a town of Austria; 10 miles W. of Zitzersdorf.

WOURICHEM. See **WORCUM**.

WOVEN STOCKINGS. See **STOCKING**.

WOUGHS, in *Mines*, are the walls or sides sometimes of hard stones, and sometimes soft; when soft, the miners say they are rotten: these are the bounds of an entry. Betwixt them all sorts of earth, stones, and ore lie; or, as philosophers say, grow.

WOULD, or **WELD**, among *Dyers*. See **WELD**, and *DYER's Weed*.

WOULD, in *Agriculture*, a term applied in some cases to signify an open uninclosed tract of country.

WOULD Land, that which remains in the state and condition of would. There is much of this sort of land in many counties and districts of this country which might be still greatly improved and converted to far better purposes than at present, by simply inclosing them and turning them into a state of proper and suitable cultivation. This has been already done with large tracts in Yorkshire and Gloucestershire to very great benefit, and the same may be the case with many others in different places. See **WASTE Land**.

WOULDS, a term applied by some writers on husbandry to crops of the woad kind. See **WOAD**.

WOULDING. See **WOOLDING**.

WOULMARA, in *Geography*, a town of Bengal; 28 miles S. of Midnapour.

WOUNDS, in *Surgery*, constitute the most ancient and important branch of it, accidental injuries of this kind having in all probability preceded the existence of many of the diseases to which mankind are now liable. The turbulent and enterprising spirit of the earliest generations soon produced wars, and the effusion of human blood; and even the natural habits of every people, in a state of inferior civilization, would conduce to the receipt of wounds, since the chase,

by which food was so commonly procured, would itself cause many accidental hurts. Surgeons usually define a wound to be a solution of continuity, or a division of the soft parts, more or less recently produced, commonly attended with a greater or lesser degree of hemorrhage, and almost always occasioned by an external mechanical cause.

There are some chirurgical writers who make objections to defining a wound to be a *recent* and *bleeding* division of the soft parts, and M. Richerand is one of this number. He disapproves of these terms, because a wound, when long in healing, and accompanied with suppuration, cannot admit of such a definition. And he observes, that writers who have defined a wound in this way, have been obliged to call every suppurating wound, if only of three days' standing, an ulcer, which he conceives to be altogether absurd. The epithet *bleeding*, he contends, is not applicable in a general definition of wounds, since gun-shot wounds are not ordinarily followed by an effusion of blood from the divided parts. *Nosographie Chir.* tom. i. p. 2. edit. 4.

It must be acknowledged, that there is considerable difficulty in fixing the precise period when a wound should cease to be so denominated, and take the appellation of an ulcer. The wound, after several important surgical operations, is sometimes a month or two before it is entirely healed; yet, generally speaking, as long as there is a prospect of a cure within a reasonable length of time, and the cicatrization does proceed, though slowly, surgeons mostly still call the suppurating breach of continuity a wound, and not an ulcer. When, however, a wound is very long kept from healing by injudicious applications, constitutional causes, attacks of hospital gangrene, debility, &c. the case, we think, is most commonly regarded rather as a sore, or ulcer, than as a wound. An ulcer, strictly so called, does indeed seem to imply a breach of continuity arising from the process termed *ulceration*, or *ulcerative absorption*, in which a chasm, or loss of substance, is actually produced in the part by the action of the absorbent vessels. (See **ULCERATION**, and **ULCER**.) This process is also concerned in the production of every sore which is the consequence of a burn; for though parts may be at once killed, and converted into eschars by the fire itself, yet the separation of such deadened parts, or sloughs, so as to leave an ulcer behind, is the result of a process, in which the absorbents of the adjoining living surface remove the particles of matter, which form the connection between those parts which are killed and those which are alive.

In the perusal of Richerand's sentiments, who has betrayed so much delicacy and so many scruples about the admission of definitions, and who is at the same time the author of a modern system of physiology, we confess that we were rather surprised to find him insinuating upon burns, and the apertures by which abscesses spontaneously burst, being wounds, and not ulcers. In fact, he seems to regard the formation of a breach of continuity, in these cases, as entirely the result of physical and mechanical causes, and not as the consequence of a vital process, in which the action of the absorbent vessels has a very considerable share.

With respect to the propriety of the epithet *bleeding*, in the definition of a wound, there cannot be any real objection to it in a general sense; for although a wound does not bleed when in a suppurating state, yet it has almost always done so on the first occurrence of the injury. Even the generality of gun-shot wounds, though it may not be their usual nature to bleed much, commonly pour out some blood.

We have stated, that wounds are produced by external mechanical causes. There are, however, exceptions to this remark;

remark; for it sometimes happens that breaches of continuity, both in the soft and hard parts, are caused by the violent action of the muscles. Thus, the patella and os brachii are occasionally fractured by the powerful contraction of the muscles; and the muscles either tear themselves asunder, or rupture the tendons with which they are connected. Sometimes, also, the sharp point of a broken bone wounds the superincumbent integuments, and changes the case into a compound fracture. Here we see the cause is mechanical, but yet not of an external kind, as in ordinary examples.

Wounds are divided by the writers on surgery into several kinds, the distinctions being founded either upon the sort of weapon with which the injury was inflicted; or upon the circumstance of a venomous matter having been inserted into the part; or, lastly, upon the particular situation of the wound, and the nature of the wounded parts themselves. Hence we have *cuts, incisions, or incised wounds*, which are such as are produced by sharp-edged instruments, and are generally free from all contusion and laceration. The fibres and texture of the wounded part have suffered no other injury but their mere division; and there is consequently less tendency to inflammation, suppuration, gangrene, and other bad consequences, than in the generality of other species of wounds. Incised wounds also may usually be healed with greater quickness and facility than other wounds, which are accompanied with more or less contusion and laceration: the surgeon has only to prevent the solution of continuity from gaping, or, in other words, he has simply to bring the opposite sides of the wound into contact with each other, and keep them in this state a few hours, and they will unite and grow together.

Another class of wounds are *flabs, or punctured wounds*, made by the thrust of pointed weapons, like bayonets, lances, swords, daggers, &c. and also by the accidental and forcible introduction of considerable thorns, large nails, &c. into the flesh. These wounds frequently penetrate to a great depth, so as to injure large blood-vessels, viscera, and other organs of importance; and as they are generally inflicted with much force and violence, the parts suffer more injury than what would result from their simple division. It also deserves notice, that a great number of the weapons, or instruments, by which punctured wounds are occasioned, increase materially in diameter from the point towards their other extremity; and hence, when they penetrate far, they must force the fibres asunder like a wedge, and cause a serious degree of stretching and contusion. It is on this account that bayonet wounds of the ordinary soft parts are very often followed by violent inflammation, an alarming degree of tumefaction, large abscesses, fever, delirium, and other very unfavourable symptoms. The opening which the point of such a weapon makes is quite inadequate for the passage of the thicker part of it, which can only enter by forcibly dilating, stretching, and otherwise injuring the fibres of the wounded flesh.

A third description of wounds are the *contused and lacerated*, which strictly comprehend, together with a variety of cases produced by the violent application of hard, blunt, obtuse bodies to the soft parts, all those interesting and common injuries denominated *gun-shot wounds*. Many bites rank also as contused and lacerated wounds. In short, every solution of continuity, which is suddenly produced in the soft parts by a blunt instrument, or weapon which has neither a sharp point nor edge, must be a contused, lacerated wound.

Poisoned wounds are those which are complicated with the introduction of a venomous matter, or fluid, into the part.

Thus the stings and bites of a variety of insects afford us examples of poisoned wounds; but a more serious and dangerous instance, which we meet with in this climate, is seen in the cuts accidentally received in the dissection of putrid bodies, or in handling instruments infected with any irritating venomous matter; as sometimes happens to the surgeon in the performance of operations on gangrenous limbs, and in the application of dressings to venereal and other infectious ulcers. The most dangerous, however, of all the poisoned wounds, which ever occur in this kingdom, are those resulting from the bite of the viper, and from the bites of rabid animals, particularly the dog and cat. See HYDROPHOBIA.

Wounds are farther divided by surgical writers into *wounds of the head, wounds of the face, wounds of the throat, wounds of the chest or thorax, wounds of the belly or abdomen, wounds of the limbs or extremities, wounds of the arteries, wounds of the veins, &c. &c.*

Wounds may likewise be universally referred to two other general classes, *viz. simple and complicated*. A wound is called *simple*, when it occurs in a healthy subject; has been produced by a clean, sharp-edged instrument; is unattended with any serious symptoms; and the only indication is to re-unite the fresh-cut surfaces. A wound, on the contrary, is said to be *complicated*, whenever the state of the whole system, or of the wounded part, or wound itself, is such as to make it necessary for the surgeon to deviate from the plan of treatment requisite for a common simple wound. The differences of complicated wounds must, therefore, be very numerous, as they depend upon many incidental circumstances, the principal of which, however, are, hemorrhage, nervous symptoms, contusion, the unfavourable shape of the injury, the discharge or extravasation of certain fluids indicating the injury of particular bowels or vessels, the presence of foreign bodies or of a virus in the part, loss of substance, the attack of hospital gangrene, &c. See ULCER.

All large or deep wounds are attended with more or less symptomatic fever. It usually comes on, as Dr. Thomson observes, at a period varying from sixteen to thirty-six hours after the infliction of the injury. Its occurrence is indicated by an increased warmth of the skin; by increase in the frequency, and generally also in the strength of the action of the heart and arteries; by anxiety, thirst, and by the suppression of the powers of digestion. The symptomatic fever from wounds is generally of the inflammatory character; and it even sometimes happens that a very high degree of symptomatic fever occurs in debilitated constitutions, and in persons who have lost a considerable quantity of blood. In these cases, the frequency of the pulse, however, is more remarkable than its strength, and the fever which occurs seems to resemble more an asthenic fever than it does one that is truly inflammatory. It is of great consequence to attend to the type of this fever in the treatment; for the loss of blood, which may be required and sustained with impunity in the one species of fever, may prove most injurious, if not fatal, in the other. Thomson's Lectures, &c. p. 292.

We shall now proceed to offer a general description of the several kinds of wounds, and the manner of treating them; and then notice the wounds of particular parts, and the surgical measures which seem best calculated to promote their cure. As, however, *wounds of the head*, comprehending its external coverings, and the cranium and brain, form the subjects of articles already published, these cases will not fall under consideration in the subsequent columns, the reader being referred for information concerning them to

COMPRESSION, CONCUSSION, EXTRAVASATION, HEAD, *Injuries of*, and TREPANNING.

Of Cuts or incised Wounds.—Sharp-edged instruments may produce a division of the parts upon which they act, altogether on the principle of direct pressure; in which case, they may be regarded as operating in the manner of a wedge. In other instances, they both press and saw at the same time, and then the solution of continuity is made with more facility, and carried to a greater depth, because the fibres are elongated in the direction in which the instrument saws, as well as in that in which it presses.

In whatever way a cutting instrument operates, several consequences result from the division of the parts. 1st, An effusion of blood from the divided vessels. 2dly, Pain, arising from the division of nerves. 3dly, A gaping of the wound, or separation of its edges from each other.

Anatomy teaches us, that almost every part of the body is furnished with a considerable number of blood-vessels, which indeed exist in such myriads, that it is impossible to prick the skin with the point of the most minute needle, without opening one or more ramifications of vessels containing blood. But this effect always happens in a still greater and more remarkable degree, when the division, caused by a sharp-edged instrument, is at all extensive.

If the wounded vessels are of small size, the blood issues from them only in moderate quantity; but when they are large, the hemorrhage is more copious, and it may be so rapid as to prove almost instantly fatal. Many of the phenomena of hemorrhage have been already considered in another place (see HEMORRHAGE); and, on this account, we shall not have occasion now to travel over the whole of that interesting topic again. There are, however, certain parts of the subject which must fall under consideration in the course of this article; and in mentioning them, we shall take the opportunity of noticing a few ingenious suggestions, which have been made since the period when the above-mentioned article was written, and which, when further investigated, may lead to very important improvements in the treatment of wounds.

It has been stated, that hemorrhage is one of the circumstances which render wounds complicated; yet it is to be understood, that when the bleeding is not so considerable as to hinder the union of the parts, and a further effusion of blood can be prevented by the very same pressure which is necessary to promote this union, the case is always regarded as a simple wound. Such is that which is produced by the operation for the harelip, &c.

The same experiment which demonstrates the presence of blood-vessels in every situation, namely, pricking any part of the body with a needle, proves also that filaments of the nerves are found every where, and at every point; for the slightest prick of the skin occasions pain, and pain cannot happen except where there are nerves. But wounds are observed to be attended with a pain, which is more or less acute, according to the kind of cutting instrument with which they are inflicted, the extent of the division, and especially according as the wounded person happens or not to be in expectation of the receipt of the injury. A patient, on whom an operation is to be performed, turns his whole attention to the effect which the use of the knife will produce upon his feelings, and he suffers a great deal; but if an incision be made when not expected, or a soldier be wounded in the heat of battle, the injury is sometimes not perceived till the bleeding attracts notice.

Immediately a part is divided with a cutting instrument, the edges of the wound separate more or less distantly from each other, and the injury presents a gaping appearance.

This is an occurrence which is owing to several causes, necessary to be understood by every surgeon who is desirous of knowing the best mode of obviating it.

The first cause of the separation of the lips of a wound from each other is, no doubt, the thickness of the instrument with which the solution of continuity is made. A cutting instrument, acting like a wedge, must unavoidably separate the parts between which it enters; but if this were the only cause, the gaping of a wound would be very inconsiderable, since the blades of most cutting weapons are extremely thin. We find, however, that the opposite surfaces of many wounds are drawn away from each other several inches, and the causes to which the phenomenon is to be ascribed are the elasticity and contractile nature of the divided parts; sometimes one of these properties operating singly, sometimes both of them together in the same wound.

Elasticity is a quality which belongs to all animal substances, and it is inherent in them even after they have been deprived of life; but it does not prevail in an equal degree in every texture. Thus, the gaping of a wound depending upon this cause varies very considerably, according to the nature of the divided parts. The edges of an incision made in the skin become widely drawn asunder, because the integuments are endued with great elasticity. The cellular membrane, when cut, gapes very little, because it is less elastic. The muscles also are not remarkably elastic; yet wounds of them, especially transverse wounds, always have their opposite sides separated a vast distance from each other: but this is a circumstance which is owing not altogether to the elasticity of the parts, but partly to their contractile powers.

The separation of the edges of a wound is not always in proportion to the elasticity of the wounded part; it is likewise proportioned to the tension of this part at the very moment of the injury. An exceedingly simple experiment proves the truth of this observation: if the skin which covers the knee be divided transversely in the dead subject, while the leg is bent upon the thigh, and another similar incision be made in the other knee, while the leg is extended, the separation which happens between the edges of the division will be found to be much greater in the first than in the second example.

The contractile power, or irritability, which is a peculiar property of muscular fibres, and by virtue of which they tend continually to shorten themselves, is the most powerful cause of the separation which occurs between the opposite sides of a transverse wound of any muscle. The separation thus produced is the greater in proportion as the cut muscular fibres are longer, inasmuch as the contraction of which the muscles are capable, by reason of their contractile power, is itself in a ratio to the length of the muscular fibres. Thus, as Boyer observes, if two muscles be divided transversely, the fibres of one of which are three times as long as those of the other, the separation which takes place between the edges of the wound of the former will be three times as great as what follows, between the sides of the division made in the latter.

The force with which the separation is produced by the contractile power of the muscles, is not in proportion to the length of the muscular fibres, but to their quantity. Each muscular fibre being regarded as a separate distinct power, it is obvious, that the more these powers are multiplied, the greater must be the effect resulting from their action.

It appears also, that in addition to the first contraction of a divided muscle, a secondary and increased contraction of the part may be excited, when it is exposed and irritated.

From what has been stated, it seems then that in wounds of parts destitute of contractile properties, as the skin, cellular membrane, ligaments, fasciæ, &c. their elasticity is the only cause of such wounds gaping, or of the separation which happens between the opposite surfaces of the injury; but that in muscular wounds the separation is the effect both of the contractile and elastic powers of the part. Hence, as we have already observed, the separation is greater the more tense the muscle is at the instant when the wound is inflicted.

“The edges of every incised wound (says professor Thomson) are more or less retracted, or drawn from each other, and this generally in proportion to the size of the wound, and the nature of the parts upon which it is inflicted. The different soft textures of which the human body is composed are more or less elastic, and are in the healthy condition of the body kept in a certain degree of tension. When the fibres, therefore, of any of these textures are divided, they recede from each other; those of skin farther than those of cellular membrane, and those of muscle farther than those of skin. The fibres of muscle contract most of all. The extremities of a divided artery recede considerably from each other; the veins less than the arteries, and the nerves probably less than the veins. To oppose this contraction of divided parts by suitable means, is one of the main objects which the surgeon proposes to himself in the cure of wounds; for the retraction of the edges of wounds from each other always prevents re-union by the first intention, and very often retards it for a long time by the second.” See Thomson’s Lectures on Inflammation, p. 280; also *UNION by the First Intention.*

The prognosis of wounds made with a cutting instrument varies according to the extent and depth of the division, the nature of the injured parts, and the circumstances which attend the accident. Deep large wounds are more dangerous and more difficult to cure than those which only interest the skin. Wounds, accompanied with injury of considerable vessels or nerves, are more or less dangerous, according to the magnitude or number of those vessels or nerves. Simple wounds, in which the only indication is to bring the divided parts together, so that they may re-unite, are the most favourable cases of all. On the other hand, complicated wounds are more or less hazardous, according to the particular nature of the complication. In the prognosis of wounds also, we must not forget to take into consideration the patient’s age, his kind of constitution, and the diseases under which he may labour. Generally speaking, the most dangerous examples of incised wounds are those which are made about the throat by persons who attempt to destroy themselves. Here there are so many large blood-vessels, nerves, and other parts of great importance, that deep incised wounds too often prove fatal, either immediately, or in the course of a few days. Sometimes the patient opens the carotid artery, and perishes of hemorrhage on the spot, before any assistance can be rendered. In other instances, he divides some of the principal branches of the external carotid, and after losing a great deal of blood he faints, and the hemorrhage spontaneously ceases for a time. The fainting indeed is often the very thing which saves his life, by checking the effusion of blood until a surgeon arrives; who ties the vessels as soon as they begin to bleed again. Cut wounds of the extremities, when such arteries as the femoral and brachial are injured, may also suddenly destroy the patient, by the great quantity of blood which is sometimes lost before the arrival of surgical assistance.

A surgeon, called to a recent cut or incised wound, has

three objects which he should endeavour to accomplish without the least delay.

The first, and that which requires his immediate interference, is the bleeding, which must be checked, or the patient may lose his life in a few minutes.

The second is the removal of all extraneous matter, foreign bodies, &c. from the cavity of the wound.

The third is to bring the opposite surfaces of the wound into even contact, and to adopt proper measures for keeping them in this position, until they have grown together again.

1. *Hæmorrhage.*—For an explanation of the means which nature employs in the suppression of bleeding from divided arteries, as well as for an account of the best surgical measures for promoting this object, and a detail of numerous observations on the principles by which the conduct of the surgeon should be regulated in the use of the ligature, we beg to refer to the articles *HEMORRHAGE* and *LIGATURE.*

In the present place we shall briefly notice how the surgeon ought to act in cases of incised wounds, accompanied with hemorrhage, without passing over, however, a few things which have been suggested since the above-mentioned articles were written.

It has been stated, that in every wound the bleeding is the thing which demands the earliest attention; because if loss of blood be not prevented without delay, the patient will frequently die in the course of a few seconds, or minutes. Every other consideration may be deferred; but when large vessels are injured, they must be immediately secured, or else the sudden death of the patient will leave the surgeon no opportunity of exhibiting his skill and usefulness in other matters connected with the treatment.

It is not, however, every bleeding which is thus serious and alarming; for the slightest and most superficial cuts are always attended with some effusion of blood. When the divided vessels are of inferior size, the bleeding soon spontaneously ceases, and no surgical measures need be taken on this particular account. When the wounded vessels are even somewhat larger, and their situation is favourable for compression with a bandage, it is often advisable to close the wound, and apply a compress and roller, instead of having recourse to ligatures, which always produce irritation, suppuration, and an obstacle to the union of that part of the wound in which they lie. Yet, let the surgeon, before he determines to trust to pressure, be well assured, that the bleeding can be thus perfectly and safely commanded without the employment of ligatures; for by the failure of compression, hemorrhage has often been renewed from time to time, and many a life been lost. We therefore wish it to be distinctly understood, that in almost all cases of considerable bleeding, the patient will not be safe unless the vessels be tied, and that the only exceptions are a few instances in which the bleeding arteries can be effectually compressed against a subjacent bone, and are not of very large size. In all other examples, tying the bleeding vessels is the only safe mode of proceeding. When the artery is of large diameter, and its mouth can be readily seen, the most proper instrument for taking hold of it is a pair of arterial forceps. With this instrument, the end of the vessel is to be drawn out a little way from the surrounding flesh, in order that a ligature may be put round it without the inclusion of any other parts, which would be unnecessary, painful, and on several accounts disadvantageous. In applying the ligature, the surgeon must take care to pull its two ends in such a manner that the noose will not rise above the mouth of the vessel; and, for the purpose of altering the direction of the force

force employed in drawing the ligature, the ends of the thumbs are found most convenient. When the bleeding arteries are not very large and distinct, they are generally taken up with a tenaculum; and of late years a double tenaculum, the points of which shut together, like the blades of a pair of forceps, has been occasionally used, and we have heard some well-informed surgeons speak highly of the invention, which we believe was originally made by professor Asfalini, an ingenious surgeon at Milan, in Italy.

The ligatures having been applied, one end of each is to be cut off close to the knot, in order to diminish the quantity of extraneous matter in the wound.

When a large artery, like the brachial or femoral, is opened, but not cut through, it often happens that the surgeon cannot get at it without making a dilatation of the wound, and bringing the wounded part of the vessel more fairly into view. In cases of this description, the first duty of the practitioner is to compress the artery above the wound, and apply a tourniquet. Thus he will put an immediate stop to the bleeding; but if he omit this essential step, the vessel will continue to bleed so profusely and rapidly, that in the inevitable obscurity and confusion thence resulting, the patient may actually lose his life before the vessel is secured. When, however, a tourniquet has been applied, the surgeon can examine the wound, and search for the artery with much greater success, as now the state of things is no longer concealed under a continual stream of blood.

As soon as the wounded portion of the artery is discovered, it ought not to be extensively dissected and separated from its surrounding connections in order to let the surgeon pass his finger under it. This mode of proceeding is now acknowledged by some of the best surgeons to be unnecessary and injurious; and it will be quite sufficient to separate the artery sufficiently to pass an eye-probe or aneurismal needle under it, with which a double ligature is to be drawn beneath it. The probe or needle having been cut off, one ligature is then to be tied above the aperture in the artery, and the other below it. Were only a single ligature applied above the wound in the artery, the bleeding would still be kept up, because the blood passes into the lower continuation of the vessel through numerous large anastomoses, in a quantity that is truly surprising.

The principles which should guide the surgeon in the use of the ligature, were not known until the late Dr. Jones published his valuable treatise on hemorrhage. As an able surgeon has observed, "he has banished the use of thick and broad threads, of tapes, of reserve ligatures, of cylinders of cork and wood, linen compresses, and all the contrivances, which, employed as a security against bleeding, only served to multiply the chances of its occurrence." Lawrence in *Medico-Chir. Transf.* vol. vi. p. 162.

In the article *SURGERY*, we have noticed the method of cutting off both ends of the ligature close to the knot on the face of the stump, with a view of lessening the quantity of extraneous matter in the wound, and promoting a complete union of the divided parts, without any suppuration. The period of the first invention of this method appears uncertain. Mr. Hennen, who seems to have been the first who adopted the method in the army, had it suggested to him in 1813 by a Mr. Hume, as the practice of some American naval surgeon; and he has since found that it had been done in Scotland 16 years before the above year. Dr. Ferguson also saw the practice adopted in Sweden as early as the peace of Amiens. Mr. Hennen mentions 34 amputations, in which this treatment was followed by suc-

cess. His accounts are highly in favour of the method. See Hennen's *Military Surgery*, p. 189, &c.

This plan has been tried by Mr. Lawrence: "The method I have adopted (says this gentleman) consists in tying the vessels with *fine silk ligatures*, and cutting off the ends as close to the knot as is consistent with its security. Thus the foreign matter is reduced to the insignificant quantity, which forms the noose actually surrounding the vessel, and the knot by which that noose is fastened. Of the silk which I commonly employ, a portion sufficient to tie a large artery, when the ends are cut off, weighs between $\frac{1}{100}$ th and $\frac{1}{80}$ th of a grain: a similar portion of the thickest kind I have tried weighs $\frac{1}{100}$ th of a grain, and of the slenderest $\frac{1}{1000}$ th."

Mr. Lawrence states, that the kind of silk twist which is commonly known in the shops by the name of dentist's silk, and which is used in making fishing-lines, is the strongest material, in proportion to its size, and therefore the best calculated for our purpose, which requires considerable force in drawing the thread tight enough to divide the fibrous and internal coats of the arteries. This twist is rendered very hard and stiff by means of gum, which may be removed by boiling it in soap and water; but the twist then loses a part of its strength. The stoutest twist which Mr. Lawrence has used, is a very small thread compared with ligatures made of inkle. The quantity of such a thread necessary for the noose and knot on the iliac artery weighs $\frac{1}{100}$ th of a grain; or, if the gum has been removed, about $\frac{1}{100}$ th. But the finest twist kept in the silk shops is strong enough in its hard state for any surgical purpose; and the noose and knot, according to Mr. Lawrence's statement, would not weigh $\frac{1}{100}$ th of a grain.

It farther appears from the report of this gentleman on the subject, that there is no danger of these ligatures cutting completely through the vessel, as some surgeons have apprehended; and that although he has not yet ascertained what becomes of the pieces of ligature after the wound is united, he has never seen abscess nor any other bad symptom occasioned by them. At the time when Mr. Lawrence wrote, he had employed this method of securing the arteries in ten or eleven amputations, in six operations on the breast, and in the removal of two testicles. The cases all did well, excepting a man who lost his thigh, and who died of an affection of the lungs. See Lawrence on a *New Method of tying the Arteries in Aneurism, Amputation, &c.* in *Medico-Chir. Transf.* vol. vi. p. 156, &c.

It merits notice, however, that the proposal of cutting off the ends of the ligatures close to the artery has not received the universal approbation of surgeons; and, in particular, Mr. Guthrie, of London, and Mr. Cross, of Norwich, have urged objections against the practice. The former gentleman, at the same time, does not entirely condemn the method, but merely argues that it is liable to inconveniences, when adopted in wounds which are to be healed by the first intention. See *Obs. on Gun-shot Wounds of the Extremities*, p. 93.

Professor Scarpa also, whose experiments lead him to prefer large ligatures and intervening substances between them and the vessel, must be numbered amongst those who disapprove of the new plan. Like all his writings, the memoir which he has recently published respecting the ligature of arteries is highly interesting, and drawn up with the greatest candour.

Mr. Cross, of Norwich, is more decidedly adverse to this new practice; and he founds his objections chiefly upon some

Some experiments which were made upon animals, and which, he conceives, justify the following conclusions :

First, If the wounds do not unite by the first intention, the ligatures may escape with the discharge, without any inconvenience.

Secondly, If common ligatures of twine are cut short, the wound may unite over them, and they may be found in abscesses after an interval of many weeks.

Thirdly, If the finest darning's silk be employed in the same way, the wound uniting over it, the ligature may be detached from the vessel, and remain buried in an abscess, where it will be found at different periods, from one to seven months; and this may happen whether the vessel be firmly compressed with a single ligature, or divided between two ligatures, so as to imitate the circumstances under which vessels are tied after operations.

Fourthly, If Indian silk, fine as hair, be put round a vessel, so as to diminish its diameter, or to effect its obliteration, by just compressing its sides together, it may remain in this situation without exciting abscess, or producing any inconvenience. The ligature may be thus applied to compress an artery for the cure of aneurism; but not to secure vessels divided in operations. If a thin ligature be drawn sufficiently tight upon a vessel on the face of a stump to be secure, Mr. Crofs is persuaded, that the extremity of the vessel, which becomes insulated as it were, must die. (See London Med. Repository, vol. vii. p. 363.) In one case of amputation also, in which the practice was tried, the stump was long in healing, and several small abscesses repeatedly formed.

On the other hand, we must take into consideration, that M. Delpech, of Montpellier, has practised it to a considerable extent for several years past, without any inconvenience. M. Roux has also tried the plan in three operations on the breast; the cases did well, and no ill consequences arose from the presence of the bits of thread under the cicatrix. See Relation d'un Voyage fait à Londres en 1814, ou Parallele de la Chirurgie Angloise avec la Chirurgie Française; Paris, 1815, p. 134—136.

Mr. Hennen, in answer to Mr. Guthrie, also observes, that in the cases where it was tried at Bilbao, "neither pain, heat, nor tumour, febrile exacerbation, nor formation of pus, could be fairly traced to the short cut ligatures, which would not in all human probability as readily have succeeded to the ligatures usually employed; while, on the contrary, the progress of healing has been sensibly more rapid where they have been used." *Obs. on Military Surgery*, p. 193.

Since Mr. Lawrence communicated to the Medical and Surgical Society of London the description of a "New Method of tying the Arteries in Aneurism, Amputation, and other Surgical Operations," he has constantly employed the method therein proposed, both in St. Bartholomew's hospital and in private practice; and, as he informs us, he has now tried it in many operations of almost every description. "The general result of my experience is (says he), that this plan, by diminishing irritation and inflammation, and simplifying the process of dressing, very materially promotes the comfort of the patient, and the convenience of the surgeon, while it has not produced ill consequences or any unpleasant effect in the cases which have come under my own observation.

"I have found in my own practice, what has been confirmed by others, who have communicated to me the result of their experience, that the small knots of silk generally separate early, and come away with the discharge; that where the integuments have united by the first intention, the

ligatures often come out rather later, with very trifling supuration, and no painful inflammation; and that, in some instances, they remain quietly in the part.

"In two or three instances, I have been told that the ligatures seemed to have caused irritation and pain. These were amputations; and we are accustomed to see effects, quite as considerable as were alluded to here, produced by the state of the bone and other causes, where the ordinary method of securing the arteries is practised; so that I could not, on close inquiry, find any reason to ascribe what was complained of to the use of the silk ligatures, and the practice of cutting off their ends close to the knots." *Medico-Chir. Transf.* vol. viii. p. 490.

Mr. Lawrence contends, that under some circumstances the method will be attended with peculiar advantages, as in crowded military hospitals, where the destructive hospital gangrene either exists, or may make its appearance. Every measure tending to accelerate the union of wounds, whether after operations or under other circumstances, is of great importance in averting the probability of this calamitous occurrence.

This mode of cutting off both ends of the ligature close to the knot has now been successfully applied to operations for aneurism. Mr. Lawrence has himself found it answer his expectations; and we learn, that Mr. Carwardine, of Thaxted, tied the femoral artery with a small silk ligature, in a case of popliteal aneurism, and cut off the ends close to the knot. The wound united entirely by the first intention, not a particle of pus having been formed at any time; and it continued perfectly found at the distance of some months from the operation. *Op. cit.* p. 492.

If this practice prove generally beneficial in operations for aneurism, there can be no doubt it will also be advantageous in other cases, in which the surgeon is called upon to cut down to and take up punctured or partially divided arteries in accidental wounds.

Although doubts are yet entertained by some practitioners, whether this new method of applying ligatures is entitled to praise and imitation, all surgeons are unanimous about the propriety of lessening as much as possible the quantity of extraneous bodies in wounds: hence, even they who disapprove of cutting off both ends of the ligature close to the knot, sanction and adopt the practice of cutting off one-half of each ligature close to the vessel, as the other portion will suffice for the removal of the knot and noose as soon as they are detached from the tied artery. When the wound is brought together, the ligatures are to lie in the nearest interspaces left between the plasters.

2. *Of the Removal of Clots of Blood, extraneous Substances, foreign Bodies, &c. from the Wound.*—This forms the second indication to which the attention of the surgeon is particularly required, when he is first called to an incised wound. It is, indeed, an object of very material importance, because if it be not attended to, the wound may be brought together as nicely, as accurately, and as skilfully as possible, and every thing look well in the beginning; yet that desirable event, union by the first intention, will not follow, but instead of it a severe degree of pain, considerable swelling of the circumference of the injury, extensive redness, and suppuration and abscesses. All these severe and untoward consequences arise from the irritation produced by the presence of foreign bodies in wounds; and as an incised wound can generally be examined with the utmost facility, and made properly clean, without putting the patient to much pain, the neglect on the part of the surgeon becomes the more blameable. In other deep, narrow, lacerated wounds, and in many gun-shot injuries, it is often difficult at first to ascertain

tain whether there are extraneous substances in the flesh or not; but in open incised wounds no such difficulty and obscurity prevail, and the practitioner who closes them, without having assured himself that they are perfectly free from all extraneous matter, betrays either the most supine negligence, or an utter ignorance of his professional duty. It is true an incised wound made with a clean, sharp instrument, which has not broken, can obviously have no foreign bodies in it. But very considerable and dangerous cuts are often produced by glass, china, &c. which are apt to break at the moment, and leave some of their fragments in the part. Sometimes also the weapon with which the wound is made is unclean, and occasionally dirt, gravel, &c. get into the wound, in consequence of the patient falling upon the ground at the time when he receives the injury. We shall merely repeat, that as extraneous bodies operate as an irritation to all kinds of wounds, the surgeon ought to take care to remove them immediately the bleeding vessels have been secured.

Mr. John Hunter believed, that blood retaining the living principle was rather an useful substance in the union of wounds than otherwise; and he only considered blood, which had been deprived of this principle by long exposure, the effect of styptics, &c. as hurtful, when left on the surface of the wound. Yet this is a doctrine which is by no means sanctioned by the approbation of the best modern practitioners, all of whom are decidedly of opinion, that leaving any blood upon the surface of a recent wound, when the opposite surfaces of such wound are to be brought into contact, is disadvantageous, retarding the cure, and rendering union by the first intention less certain. The presence of blood in the cavity of the wound, indeed, must have the effect of producing a greater or lesser separation of those surfaces, which ought strictly to touch each other; and we decidedly believe, that the practice of freeing wounds as much as possible from clots of blood may be successfully defended both upon theoretical and practical principles.

3. *Union of the Wound, Dressings, &c.*—We have said, that when the surgeon has stopped the bleeding, removed extraneous substances, and properly cleaned the wound, the next indication is to bring the opposite sides of the injury into contact with each other, and keep them quietly and steadily in this position until they have grown together again. Wounds are healed by two processes; viz. by one, in which pus is produced, and granulations and new skin are formed; and by another, in which, if it perfectly and universally succeed, no suppuration whatsoever takes place. The latter, when it can be practised, is always the most desirable, because it is not only the quickest means of cure, but also the most perfect; the part being covered by the old original skin, which is always stronger and less disposed to ulceration than what is new formed. Surgeons have termed this way of healing wounds *Union by the First Intention*, (see these last words,) or *Adhesion*; and Mr. Hunter named the process by which it, together with many other analogous effects, was accomplished in the animal body, the *Adhesive Inflammation*. See INFLAMMATION.

The great recommendations of union by the first intention are, celerity of cure, the diminution of the pain and inflammation arising from the exposure of raw surfaces, freedom from the inconveniences of suppuration, the prevention of the deformity, which would otherwise result from a large cicatrix, and the greater permanency and soundness of the cure, for the reasons above stated.

The strong tendency which divided parts of the animal body have to grow together, when kept a certain time in contact with each other, is an important fact, of which the

moderns have taken much more advantage than the ancients. There are even cases and experiments on record in support of the opinion, that it is not entirely impossible for parts entirely detached from the rest of the body to become united again, if quickly replaced. In the article *UNION by the First Intention*, we have noticed the interesting experiments made by Duhamel and Mr. Hunter. The researches of the latter celebrated philosopher brought to light several very curious and instructive facts. He proved that the testicles of a cock, when removed and introduced into the abdomen of a hen, contracted a vascular connection with the surface of the viscera, and lived. He ascertained, that a sound tooth might be transplanted from its socket, and acquire an union to the alveolar process of another person. He also cut off the spurs of a young cock, and found that they might be made to unite to its comb, or that of another cock, and grow in such situation. The possibility of this species of union shews how strong the disposition of the fresh surfaces of an incised wound must be to grow together; particularly when it is considered, that in the foregoing and in some of the following instances, there can be on one side no assistance given to the union, as the part entirely separated from the rest of the body is hardly able to do more than preserve its own living principle, and (as Mr. Hunter expresses himself) accept of union.

The following observations on this subject are taken from professor J. Thomson's excellent book on inflammation: "Besides those examples that are seen in the transplantation of the teeth, it must be confessed, that instances of re-union among parts which had been entirely separated are very rare in the human body; so rare, indeed, that most practitioners still treat with disbelief and ridicule the few instances which have been put upon record. But the different facts which have been learned respecting the transplantation of the teeth, together with the experiments of Duhamel and Mr. Hunter, prove indisputably the possibility of parts being re-united which have been completely separated from the animal system to which they belonged, and in which the circulation of the blood must necessarily have ceased for a time. There is nothing therefore in the nature of the fact recorded, that can justify us, I conceive, (says Dr. Thomson,) in doubting the veracity of those, by whom similar instances of re-union between other parts of the body have been related.

"That practitioners have generally failed in effecting this re-union, is frankly acknowledged by those who have related cases so very extraordinary. I shall mention to you (continues this author) a few of those rare cases, and leave it to your own judgment to deduce from them the conclusions, which the characters of the authors by whom they are related, and the nature of the facts themselves which they relate, may seem to you to warrant.

"The first example of this kind which I find distinctly recorded is by Phiorovant, in the 54th page of his second book of the *Secrets of Surgery*: 'In that time, when I was in Africa, there happened a strange affair: a certain gentleman, a Spaniard, that was called Il Signior Andreas Gutiero, of the age of twenty-nine years, upon a time walked in the field, and fell at words with a soldier, and began to draw. The soldier seeing that, struck him with the left-hand, and cut off his nose, and there it fell down in the sand. I then happened to stand by, and took it up, and pissed thereon to wash away the sand, and dressed it with our balsamo artificiato, and bound it up, and so left it to remain eight or ten days, thinking that it would have come to matter; nevertheless when I did unbind it, I found it fast conglutinated, and then I dressed it only once more, and he was perfectly whole, so that all Naples did wonder thereat, as is well

known; for the said Signior Andreas doth live, and can testify the same."

"Blegny, in his *Zodiacus Medico-Gallicus*, for the month of March, 1680, mentions a case, in which a nose that had been cut off with a fabre was replaced by a military surgeon of the name of Winsault, and in which a perfect re-union was obtained, he affirms, by the use of stitches, and of agglutinating plasters.

"A third case of the same kind is related by Garengot, at the 55th page of the third volume of his *Operations of Surgery*. 'In the month of September, 1724, a soldier of the regiment of Conti, coming out of L'Epée Royale from an inn, at the corner of the street Deux-Ecus, was attacked by one of his comrades, and in the struggle had his nose bitten off, so as to remove almost all the cartilaginous part. His adversary perceiving that he had a bit of flesh in his mouth, spat it into the gutter, and endeavoured to crush it by trampling upon it. The soldier, who on his part was not less spirited, took up the end of his nose, and threw it into the shop of M. Galin, a brother-practitioner of mine, till he should run after his adversary. During this time, M. Galin examined the nose that had been thrown into his shop, and as it was covered with dirt, he washed it at the well. The soldier returning to be dressed, M. Galin washed his wound and face, which was covered with blood, with a little warm wine, and then put the extremity of the nose into this liquor to heat it a little. Having in this manner cleansed the wound, M. Galin now put the nose into its natural situation, and retained it there by means of an agglutinating plaster and bandage. Next day the re-union appeared to be taking place; and on the fourth day, I myself dressed him with M. Galin, and saw that the extremity of the nose was perfectly re-united and cicatrized.'

"These (says professor Thomson) are the only cases which I have been able to find distinctly stated of the re-union of a nose which had been completely cut off. This event, from analogy, we have reason to believe is possible, and nothing short of a contrary testimony in the instances I have related could justify us, I conceive, in denying the truth of the fact."

Dr. Thomson then details a case, extracted from vol. xxxiii. of the *Journal de Médecine*, where the point of a finger which had been cut off was re-united by M. Bossu, surgeon at Arras. Dr. Thomson also mentions, that he has been informed by different persons entitled to credit of a considerable number of cases similar to the preceding, in which the points of fingers and toes completely separated were afterwards re-united.

Although it must be acknowledged that the foregoing cases of the union of parts completely severed from the body are uncommon, the same observation does not apply to instances in which the detached part still retains a partial and slight connection with the rest of the body, by means perhaps of only a few fibres or little bit of skin. "Many cases," says Dr. Thomson, "are upon record, and many more have been observed, in which parts have re-united, which were divided all to a very small portion of cutis,—a portion so small that it is not easy to conceive that any effectual circulation could be carried on through it; and in these cases it deserves to be remarked, that it was generally the nose, or the extremities of the fingers and toes, which re-united, after having been separated and replaced. I have seen two examples of the re-union of the nose, where it was almost entirely separated. In one of them it adhered only by the skin of one of the alæ, and in the other chiefly by the septum. Arcæus mentions a case in which the nose, with most of the upper jaw, was so separated as to hang

down upon the chin, and yet a re-union was effected. A case is mentioned by Lombard, in which the nose, nearly cut off and unreplaced for some hours in winter, was made to re-adhere by stitching and proper dressings. Another case of the same kind occurred to Loubet." (*Lectures on Inflammation*, p. 243.) In the *Dictionary of Practical Surgery*, an instance is mentioned, in which an ear that had been completely separated from the head, with the exception of a small bit of skin, was united again with the aid of a future; and Dr. Thomson has himself seen portions of the little toe and little finger, after being nearly cut off, successfully re-united.

The knowledge of all these facts cannot but prove useful in the practice of surgery, inasmuch as it teaches the practitioner to attempt the union of parts, under circumstances which would otherwise appear entirely hopeless and discouraging.

In promoting union by the first intention, surgery is merely to officiate as the handmaid of nature. There are only two indications to be fulfilled: the first is to bring the edges of the wound into reciprocal contact, and keep them so; the other is to avert the access of immoderate inflammation, by which the agglutination of the wound would certainly be prevented. The first object is accomplished by a proper position of the wounded part, by bandages, by adhesive plaster, and by futures. The second is fulfilled by a strict observance of the antiphlogistic regimen, and particularly by avoiding every kind of motion and disturbance of the wound. The rest is the work of nature.

The position of the part is to be regulated on the principle of relaxing the wounded integuments and muscles. If the extensor muscles are injured, the joints which they move ought to be placed in an extended posture; if the flexor muscles are wounded, the limb is to be bent. When the integuments alone are cut, the same posture which relaxes the muscles situated immediately beneath the wound also serves in general to relax the skin. In transverse wounds of muscular fibres, it is astonishing what immense effect the observance of a proper posture produces. This is never to be neglected, whatever may be the other means adopted.

Bandages may frequently be made to contribute very essentially to keeping the sides of wounds duly in contact with each other. This is strikingly illustrated in cases of harelip, where we see that the opposite edges of the fissure may be brought forward so as to touch, and be maintained in this position by the simple use of compresses and a bandage. Such was the mode of treatment preferred by M. Louis after the operation for the harelip, and were it not for the greater convenience and certainty of the twisted future, it is the plan to which surgeons would yet have recourse. (See HARELIP.) The *uniting*, or, as it was formerly named, the *incarnative bandage*, is one which operates in keeping the opposite surfaces of wounds accurately applied to each other, so that the opportunity may be afforded for them to unite and grow together again. The common uniting bandage can only be used in wounds which take a direction corresponding to the length of the body or limbs, and which are situated where a bandage can be employed with convenience and effect. It consists of a double-headed roller, having a slit between the two heads. The slit must be sufficiently large to allow one head of the roller to pass through it with facility. The wound having had the requisite dressings put on it, the surgeon is to take one head of the roller in each hand, and apply the bandage to that part of the limb which is opposite the wound. One head of the roller is then to be brought round, so as to bring the slit over the breach of continuity. The other

head is then to be brought round in the opposite direction, and passed through the slit. The bandage is now to be drawn moderately tight, and its two heads being carried round the limb again, the same artifice is to be repeated. A sufficient number of turns of the roller must be made to cover the whole length of the limb.

When the wound is deep, it is recommended to place small longitudinal compresses beneath the roller, at a little distance from the edges of the wound.

As the uniting bandage can only be made use of for longitudinal wounds, which never have a considerable tendency to gape, nothing can be more absurd than the application of it with immoderate tightness. By such cruel and injudicious practice, many a limb and life have been lost; for, if the bandage be very tight on its first application, what a dangerous constriction of the limb or part must follow, when the swelling, necessarily arising from the wound, has had time to come on. It is thus that insufferable pain, gangrene, and sphacelus, have frequently been brought on, when, if the part had been simply dressed and left unconfined, every thing would have gone on most favourably. It is right to state, however, that modern surgeons are not partial to the uniting bandage, and we freely declare our conviction, that it is a means which may very well be dispensed with in practice.

If it has any advantages, they consist in its having more power than the adhesive plaster alone to maintain the opposite sides of deep wounds in contact, and in its acting without the irritation frequently arising from the application of resinous substances to the skin. It is not, however, exempt from serious inconveniences. Its total concealment of the wound, its lying in irregular folds, so as to create an uneven cicatrix, and the pressure and constriction attending its use, &c. might be mentioned. (See First Lines of Surgery, p. 68. edit. 3.) So little is the uniting bandage now employed, that although we have seen some thousands of wounds, we have not noticed its use in a single instance during the last twelve or fifteen years. When pressure can be made to assist the other dressings, surgeons almost always resort to compresses and a simple roller. In a few particular cases, in which the limb would be too much disturbed by the application and removal of a common roller, the eighteen-tailed bandage is to be preferred. See BANDAGE, and FRACTURE of the Thigh.

Adhesive plaster may be said to be the most common means employed in the practice of surgery for bringing the edges of wounds together. When used for this purpose, it was sometimes technically called by the old surgeons the *dry future*, in opposition to futures strictly so named, which are usually made with a needle, and are invariably attended with a degree of bleeding. It was at one time supposed, that adhesive plaster could be of no material use, except in superficial wounds of the skin. It is true, that adhesive plaster has no direct effect in bringing together the sides of a deep muscular wound; yet we ought to recollect, that by drawing the integuments over the deeper part of the injury, it at once prevents the continuance of the exposed state of the cut surfaces, under which suppuration would unavoidably follow. Nor does the use of adhesive plaster hinder recourse to other measures more calculated to bring the opposite surfaces of the deeper part of the wound into contact, such as the observance of a proper position, and the use of compresses and a bandage. It is also an error to suppose that adhesive plaster cannot be used in situations where hair grows, or where it will soon become wet. If the part be well shaved, and perfectly dried at first, the application will not become loose so soon as to

prove ineffectual. In such instances, the plaster should be very fresh, and its quality may be made rather more adhesive than in ordinary cases.

Adhesive plaster is generally applied in strips, between every two of which an interspace is recommended to be left, for the purpose of allowing any discharge to escape. To bring the edges of the wound effectually together, and at the same time to leave a little room for the exit of the discharge, are the objects to which we ought particularly to attend in the employment of adhesive plaster: hence, when the strips are broad, it is not unfrequent to cut out an oval piece of each strip just where it crosses the line of the wound. Equal parts of the *emplastrum plumbi*, and of the *emplastrum resinæ*, form the composition generally used in this country for adhesive plaster. They are melted over a slow fire and well mixed together, after which they are spread upon linen with a warm spatula.

Sutures, or *Stitches*, are of several kinds, but the only one which is now usually employed in the cure of wounds is the *interrupted future*. The *quilled future* is rarely used at present, though it was formerly much in favour, and is not yet passed over by systematic writers. As a description of these futures has been given in a separate article (see SUTURE), we shall not repeat the particulars of the manner of making them. The *twisted future* is not unfrequently preferred for holding together the edges of cuts in the face, where the parts are liable to be in almost constant motion, and where the avoidance of the disfigurement of a large scar is peculiarly desirable. This is the future which is always employed in the cure of the *Harelip*, in which article a description of it will be found. These, and a future called *gastroraphe*, which will be noticed in speaking of *wounds of the abdomen*, are all the kinds of futures which are ever employed by modern practitioners. The *glover's future*, or *continued stitch*, is now nearly rejected from practice, and confined to the sewing up of dead bodies; a purpose for which it is better adapted than for the union of any wound in a living subject.

On the subject of the propriety and advantage of using futures, as a means of keeping the sides of wounds in contact, much diversity of sentiment has prevailed. Some surgeons, especially M. Pibrac and M. Louis, have urgently recommended their entire discontinuance; and their observations are accompanied by facts which must have considerable weight. Their opinions and arguments, we acknowledge, have constantly influenced us in practice; and if we do not join in the sentiment, that futures ought to be entirely abandoned, we at least believe that they are still a great deal too much used. M. Pibrac and M. Louis, however, are entitled to great praise for having lessened the employment of needles in surgery; and though there are few instances in which the utility of futures appears to be confirmed by experience, there are many others in which the practice is altogether unnecessary and injudicious. "The practice of stitching," says Dr. Thomson, "is undoubtedly much less followed at present than in any former period of the surgical art; and unless in superficial wounds, where we wish to heal by the first intention, or in wounds where (as in those of the abdomen) it is necessary that the edges should not be allowed to separate from each other, the use of stitches may be, in most instances, advantageously superseded by adhesive plasters and proper bandaging. It is by limiting the use of futures, not by proscribing them altogether, that the surgeon is likely to derive advantage from the employment of means so powerful." (See Lectures on Inflammation, p. 287.) There are certainly hardly any two surgeons who think exactly alike about the cases in which futures

utures are truly beneficial or not. Thus we do not admit that they ought to be used as frequently as the remarks of the above distinguished professor would warrant; and the majority of superficial wounds, in which union by the first intention is indicated, certainly, so far from being benefited by futures, would be injured. Further observations, however, on this subject will be found in the article SUTURE.

When futures are judged necessary, their operation is always assisted by the application of suitable compresses and a bandage, the good effects to be derived from position of the part being also not neglected. The stitches ought in general to be removed between the third and seventh day; or if they are allowed to remain longer, or even in some cases so long, they excite inflammation, and sometimes ulceration.

Such then are the means which surgeons adopt for keeping the opposite surfaces of wounds in contact, until an union has taken place. When the parts grow together again without any suppuration, the mode of cure, as we have already explained, is well known to surgeons by the term *union by the first intention*. Of the nature of this process, and of the way in which a connection is established again between the parts which have been divided, we have endeavoured to give some account in a preceding volume; we shall not, therefore, expatiate on the subject. See UNION *by the First Intention*.

The first plasters and dressings applied with a view of bringing about this desirable method of cure, should be allowed to continue at least three or four days, unless any untoward symptoms, such as excessive pain, the renewal of hemorrhage, &c. indicate the contrary. The severity of the pain is sometimes owing to the future, sometimes to the immoderate tightness of the roller, and occasionally to there being extraneous substances yet lodged in the wound.

When too much inflammation is apprehended, the bandage should never be tight; and wetting it with cold water may be of use by keeping the parts cool. Perfect quietude, and the usual antiphlogistic remedies, are also not to be omitted. The old plan of covering the dressings with thick woollen rollers, caps, and large masses of tow, has now gone very much out of fashion, as being inconsistent with those principles which are recognized by every scientific surgeon as best calculated to avert and lessen inflammation.

When the first dressings are removed, the surgeon often finds union by the first intention only accomplished at certain parts of the injury; and the connection, even there, still requires further support. However, when the wound is dressed again, it is generally unnecessary to apply as many strips of adhesive plaster as were employed in the first instance. Their number may be gradually lessened at each future dressing. The futures, if there be any, should also be now withdrawn, as they will do no more good, and their continued presence may excite irritation and do harm. Suffice it to add, that throughout the subsequent treatment the rest of the dressings should be light, simple, and un-irritating.

Of the Cure of Wounds by Granulations, &c.—We remarked, that wounds are healed by two processes, one of which was not attended with the formation of pus, was the quickest and most perfect in its effects, and was called *union by the first intention*, or *adhesion*. The other process now requires description. "When, in the treatment of a wound," says professor Thomson, "the re-union by adhesion, or by the first intention, has either not been attempted at all, or, if attempted, has failed, nature brings about a cure by that slower and more complicated operation, which we now denominate the *process of granulation*; a process

termed (as we have already remarked) by Galen *re-union by the second intention*. By many of the older surgeons, this mode of healing wounds is described by the appellation of *lysarcosis*, or *concarnation*, terms perhaps less liable to objection than that of granulation, which, in strict propriety, is a term expressive of only one of the stages of this mode of re-union, and which, of course, in order to avoid all ambiguity in the language we employ, ought not to have been used as a general term for the whole. In re-union by the second intention, the edges of the wound swell and inflame more than in the process by adhesion; but, as in that process, so in this, a layer of coagulable or organizable lymph is thrown out upon the divided surfaces. This layer is soon penetrated by blood-vessels, and, like the intermedium in adhesions, (see UNION *by the First Intention*,) becomes an organized and living substance. So far these modes of re-union are similar; but in a short time after this layer of coagulable lymph has been thrown out upon the open and exposed surfaces of a wound, there is thrown out also upon the same surfaces a quantity of pus, or the matter of sores. This fluid, like the coagulable lymph, is the immediate product of a change induced in the action of the capillary vessels existing in the divided substances of the wound, a change by which they seem to become secreting instead of circulating tubes. The action by which pus is formed is now denominated *suppuration*: the old surgeons gave to it the name of *digestion*. See SUPPURATION.

"When the surfaces of the wound have been severely injured, or when the patient is of a bad habit of body, a greater or less portion of these surfaces losing its vitality, separates from the remaining sound part, and comes away in the form of a slough. The older surgeons, who are most minutely accurate in the descriptions which they have left us of diseased appearances, call this the *deterision* or *mundification* of the wound: the surgeons of the present day, *sloughing*, or the *separation of the slough*. See the article GANGRENE.

"In the healthy conditions of the body, and when the edges of the wound are uninjured, the smooth surface of the layer of coagulable lymph which covers the bottom of the wound is, in the course of a few days after the suppuration has taken place, raised into a number of small eminences, like grains or papillæ. These little eminences are termed *granulations*, and their formation in the healing of wounds, the *process of granulation*. By the older surgeons, this step, in the process of re-union by the second intention, was commonly termed *incarnation*, or *concarnation*, terms expressive of the formation of a portion of new flesh." See GRANULATION.

"On the surfaces of these granulations, but most frequently on the edges of the wound next to the skin, small white specks appear; the quantity of pus which is secreted gradually diminishes, and the blueish-white specks, by continuing to increase in number and size, come at last to cover the surface of the wound. On examination, the surface of the wound will now be found to be covered by a kind of new skin and cuticle. The formation of this new skin has long been denominated the *process of cicatrization*, and the process of re-union by the second intention being now fully accomplished, the wound is said to be completely *cicatrized*." Thomson's Lectures, p. 288.

The re-union of a wound by the first intention is the work of one, two, or three days; while re-union by the second intention always requires a period of several days, and sometimes in diseased constitutions, or parts which have been much injured, of months, or of years. Thomson, p. 290.

As the same well-informed writer remarks in another place,

place, most wounds admit of being healed partly by adhesion, and partly by the process of granulation. We have very good examples of this in the wounds made in amputation of the extremities, and in the extirpation of the mamma, or of other large tumours. We know, or at least we have reason in these instances from the first to suspect, that the whole of the wound will not heal by adhesion; but we are ignorant whether a large or a small portion will be healed by that process; and accordingly, we at first proceed in the dressing of such wounds, as if we expected or intended that the whole should heal by adhesion. We bring the edges of the wound together by adhesive straps, or stitches, and support these by proper bandaging. The adhesive straps are of great use even in those wounds in which it is impossible to bring the edges at first into contact. They bring and retain the edges near each other; they diminish the size of the wound; they keep surfaces in contact which have a disposition to adhere; and ultimately, by the gradual elongation of the old skin, even where the distances between the sides is at first considerable, they bring the separated edges to unite together. *Op. cit.* p. 293.

With respect, however, to the particular mode of dressing wounds which are to heal by granulations, it seems unnecessary to enter into any long detail in the present place; because the treatment is to be conducted on the very same principles which apply to sores, and which we have so fully explained in another article. See *ULCER*.

We shall conclude this section of the subject of wounds with a few useful rules, which professor Thomson recommends to be observed in the dressing and examination of these cases.

In examining or dressing a wound, we ought never to give the patient more pain from our modes of procedure, or methods of dressing, than is absolutely necessary for his present good and future security. For instance, we ought never to probe a wound where probing can be of no use; and we should be contented to remain ignorant of those things, the knowledge of which could only gratify an idle curiosity.

Another good rule is, to have all the fresh dressings perfectly ready before the removal of those which have been previously applied. A sponge and warm water, adhesive straps, pledgets of various ointments, lint, compresses, and bandages, are to be at hand, and not to be sought for at the very moment when they are required for use.

As in many instances the removal of the dressings, and the application of others, take up a considerable time, we ought carefully to reflect what the position is which will be most easy to the patient, and at the same time most convenient to the surgeon.

When the bandage, adhesive plaster, and other dressings, have become hard and dry, and glued together, and to the surrounding skin by blood, or other discharge from the wound, the surgeon should soften and loosen the applications by wetting them a sufficient length of time with warm water, which is to be pressed out of a sponge upon them, a basin being held below the part for the reception of the water as it falls off the dressings. This duty is of much importance in saving the patient from a great deal of agony, which the abrupt removal of the adherent dressings would produce.

In removing the dressings which are under the bandage, we must be careful that the ligatures are not entangled, and that we do not pull them forcibly away. Pulling at the ligatures during the first dressings, as professor Thomson remarks, always occasions pain; and if, in removing the

dressings, the threads be incautiously torn off, a greater or less degree of hemorrhage may be produced, and much distress, if not danger, occasioned. To avoid this accident, therefore, we ought always to search for the ligatures previous to the removal of the dressings, and to separate them from these dressings when they adhere, as they most frequently do.

Having formed and separated the ligatures, we must next proceed to remove the adhesive straps by which the edges of the wound are more immediately kept in contact. It mostly happens, that a greater or less portion of these straps is loosened from the surface of the wound by the fluid which exudes from it. This is the part, therefore, from which (says Dr. Thomson) we should first proceed to separate these straps, because it is here that the edges of the wound may be supposed to recede farthest from each other, and the pus to have found the freest exit. But the manner in which the remaining adhering portion of strap is to be separated, is not, as may first appear, a matter of indifference. There is but one way in which it can be properly taken off, though it is one which is often neglected in practice. In removing these straps, we are always to lay hold of them by the ends, first by the one, and then by the other end, and to pull them off in the direction of the wound, taking care never to raise the end of the strap much above the level of the skin, nor to continue to pull by the end we hold, after we have separated it as far as the wound. Were the straps pulled off in a direction from and not towards the wound, the edges of the injury to which they adhere would be drawn away from each other; the slight adhesions which have formed between one side of the wound and the other would be torn, and the process of re-union disturbed and retarded. If we raise the end of the strap, we also tear the edge of the wound from the subjacent parts to which it adheres.

Another good piece of advice given by professor Thomson is, that only one adhesive strap, or at most two, should be removed at once; and the part from which it has been removed being carefully wiped with the sponge, and dried with a soft linen cloth, a fresh strap is always to be applied before another is removed. It is from inattention to this rule that we see the surfaces of wounds and sores daily torn open at each dressing, merely by the weight of the parts which have just been united.

The edges of the wound, particularly if it be a large one, should always be held together by an assistant during the time of dressing.

When there are several wounds, only one is to be opened and dressed at a time, so that all unnecessary exposure of the parts may be avoided.

At each dressing care must be taken to prevent lodgments of matter, by placing the compresses and straps of plaster in the manner best adapted to press upon and obliterate any cavity in which the pus has a tendency to accumulate.

A pledget of some mild cerate or ointment is usually applied over the adhesive plaster, and its size should exceed that of the wound. It is preferable to dry lint, which becomes adherent, troublesome to remove, and often conceals and sticks to the ligatures. If lint be necessary, it may be employed over the pledget. Modern surgeons, however, are far more sparing of thick masses of lint, tow, flannel-rollers, &c. than their predecessors, as we have previously explained.

On the subject of bandages we shall here add nothing to what has been already stated in the foregoing section of this article.

In the dressing of wounds, says Dr. Thomson, particu-
larly

larly in hospital practice, where frequent change of linen is not at all times obtainable, it is of great consequence to the comfort of the patient, and to the general health and welfare of the other patients, that every attention should be paid to cleanliness, and that every thing filthy and offensive should be removed from the room or ward as quickly as possible. Above all things, care must be taken not to let the matter touch the bed-clothes.

The frequency of dressing must be regulated by the quantity and quality of the discharge from the wound, by the situation of the injury, by the climate and season of the year, by the effects which the renewal of the dressings seems to produce, and by the feelings, and sometimes the wishes of the patient.

During the long-continued discharge of pus from many wounds, the strength of the patient must be supported, and granulation and cicatrization promoted by nourishing diet and proper cordials. The most disagreeable, and unfortunately not an unfrequent termination of large wounds, is the formation of unhealthy granulations, attended with a general wasting of the body and hectic fever. See Thomson's Lectures on Inflammation, p. 294, &c.

Of punctured Wounds, or Stabs.—Punctured wounds are not only dangerous on account of their frequently extending to a considerable depth, and injuring important blood-vessels, nerves, and viscera, but they are also dangerous, inasmuch as they often give rise to violent and extensive degrees of inflammation. It is not uncommon to see formidable collections of matter follow wounds of this description, especially when the instrument with which they have been made has penetrated any aponeurosis, or fascia. Stabs and all other punctures are not simple divisions of the fibres of the body; they are attended with more or less contusion and laceration, according to the particular form of the weapon, and the degree of violence with which the thrust has been made. Hence there is not the same propensity to union by the first intention, which we observe in wounds made with sharp-edged instruments; and when ligamentous expansions are amongst the parts injured, it is not uncommon to see a train of severe local and constitutional symptoms follow. Immense agitation of the nervous system sometimes ensues upon the infliction of a punctured wound; and it has been generally attributed to the injury of tendons or nerves. This doctrine, however, is now almost quite exploded, as surgeons so frequently see nerves and tendons wounded, without the occurrence of great constitutional disorder. The truth is, that alarming nervous symptoms do not follow punctured wounds in perhaps more than five cases out of a hundred, in which tendons and nerves of some size are actually injured. It cannot, therefore, be so much the injury of these parts, as other circumstances attending stabs, which are the cause of the severe indisposition sometimes suddenly induced by such wounds. When they extend deeply, the consequences of the injury of large blood-vessels and viscera will often account for the great constitutional disorder, without having any recourse to doctrines like the foregoing.

Punctured wounds are frequently followed by the formation of deeply-seated abscesses and sinuses, and hence the cure is often difficult, and sometimes it cannot be effected till after a considerable time.

With respect to the treatment of punctured wounds, we may observe, that in this part of practice erroneous suppositions have commonly led to many serious abuses. The unqualified idea, that the severe consequences of most punctured wounds are, in a great measure, owing to the narrowness of their orifices, has induced numerous surgeons to

practise indiscriminately deep and extensive incisions, for the purpose of rendering their external communication considerably wider. To have constantly in view the conversion of such injuries into simple incised wounds has always been a maxim strongly insisted upon, and set forth as the reason of the above method of treatment. The doctrine even occasioned the frequent dilatation of punctured wounds by the still more absurd and cruel means, the employment of tents.

Certainly, if the notion were true, that an important punctured wound, such as the stab of a bayonet, is actually changed into a wound partaking of the mild nature of an incision, by the mere enlargement of its orifice, the corresponding practice would be highly commendable, however painful it might be. But the fact is otherwise: the rough violence done to the fibres of the body by the generality of stabs is little likely to be suddenly removed by an additional violence—the enlargement of the wound. Nor can the distance to which a punctured wound frequently penetrates, and the number and nature of the parts injured by it, be at all altered by such a proceeding. These, which are the grand causes of the collections of matter which often take place in the cases under consideration, must exist, whether the mouth and canal of the wound be enlarged or not. The time when incisions are proper is, when there are foreign bodies to be removed, abscesses to be opened, or sinuses to be divided. To make painful incisions sooner than they can answer any end is both injudicious and hurtful. They are sometimes rendered quite unnecessary by the union of the wound throughout its whole extent, without the least suppuration.

It is true, as is observed in a modern publication, that making a free incision in the early stage of these cases seems a reasonable method of preventing the formation of sinuses, by preventing the confinement of matter; and were sinuses an inevitable consequence of all punctured wounds, for which no incisions are practised at the moment of their occurrence, it would undoubtedly be unpardonable to omit them. Fair, however, as this reason for the use of the knife may appear to some practitioners, it is only superficially plausible, and a very little reflection soon detects its want of real solidity. Under what circumstances do sinuses form? Do they not form only when there is some cause existing to prevent the healing of an abscess? This cause may either be the indirect way in which the abscess communicates externally, so that the pus does not readily escape; or it may be the presence of some foreign body, or dead portion of bone; or, lastly, it may be an indisposition of the inner surface of the abscess to form granulations arising from its long duration, but removable by laying open the cavity. Thus it becomes manifest, that the occurrence of suppuration in punctured wounds is only followed by sinuses, when the surgeon neglects to procure a free issue for the matter after its accumulation, or when he neglects to remove any extraneous bodies. But as dilating the wound at first can only tend to augment the inflammation, and render the suppuration more extensive; and as likewise the new incision may heal up by the first intention before it has answered any purpose at all; the practice should never be adopted in these cases, except for the direct objects of giving a free exit to matter already collected, and of being able to remove extraneous bodies palpably lodged in the part. We shall once more repeat, that it is an erroneous idea to suppose the narrowness of punctured wounds so principal a cause of the bad symptoms with which they are often attended, that the treatment ought invariably to aim at its removal.

Recent punctured wounds have absurdly had the same plan of treatment applied to them as old and callous fistulæ. Setons and stimulating injections, which in the latter case sometimes act beneficially, by exciting such inflammation as is productive of the effusion of coagulating lymph, and of the granulating process, can never prove serviceable when the indication is to moderate an inflammation which is disposed to rise too high. The counter-opening, which must be formed in adopting the use of the seton, is also an objection; and though French authors have given us accounts of their having drawn their setons across patients' chests, in cases of stabs, they will find some difficulty in making the practice seem unattended with harm, much less productive of good. The candid and judicious surgical reader should not always think a plan of treatment right because the patient gets well; for there is an essential difference between a cure promoted by really useful means and an escape, notwithstanding the employment of hurtful ones.

For our own part, we cannot see what good can ever possibly arise from the use of setons in cases of punctured wounds. Will a seton promote the discharge of foreign bodies, if any happen to be present? By occupying the external openings of the wound, will it not be more likely to prevent it? In fact, will it not itself act with all the inconveniences and irritation of an extraneous substance in the wound? Besides, let it be recollected, that punctured wounds are rarely accompanied with the lodgment of foreign bodies. Is a seton a likely means of diminishing the immoderate pain, swelling, and extensive suppuration so often attending punctured wounds? It will undoubtedly prevent the external openings from healing too soon; but cannot this object be effected in a better way? In most instances where much matter is collected, and where the suppuration is likely to last a long while, in consequence of exfoliations, there will be no chance of the sinus healing up prematurely; and if such risk should appear probable, it is always easy to maintain an external opening by the daily introduction of a probe into the sinus, and a small dossil of lint into its orifice. See *First Lines of Surgery*, edit. 3. chap. xvi.

When a surgeon is called to a punctured wound or stab, he may often form some opinion respecting the depth and nature of the injury by examining the weapon with which it was done, and observing how far the blood reaches along the blade from the point, and by attending to the quantity and quality of the fluids which may issue from the external opening. Thus, the escape of chyle or feces will denote that the bowels are injured; the effusion of urine will indicate that the bladder or some part of the urinary organs is wounded; and the flow of much arterial blood will prove that a considerable artery is opened. Wounds of the lungs will also be attended with particular symptoms, as we shall notice in speaking of wounds of the chest. In many instances, however, important viscera and large deep-seated arteries are injured by stabs, and yet no information can at first be deduced respecting what has happened from attention to local symptoms alone. The faintness and great sudden prostration of strength, the faltering, low, and intermitting pulse, the vomiting or coughing up of blood, and the coldness of the extremities, however, are still sufficient evidence that the case is complicated with injury of important organs, and that the patient is in a state of urgent danger. These are matters which will be best understood when we come to the consideration of wounds of the chest and belly, and therefore we shall not dwell upon them at present.

From what has been already stated, the reader must be aware that we do not follow the bulk of surgical writers in recommending the indiscriminate dilatation of the orifices of

punctured wounds; nor do we admit the propriety of using the knife for the purpose of preventing mischief only expected and apprehended, but not actually existing. Whenever we have had an opportunity of attending bayonet or other punctured wounds, unattended with any particular complication, we have always observed nearly the same principles as are now so generally approved of in cases of gun-shot wounds. We have abstained from dilating the orifice of the injury, except when it was necessary either to get at a bleeding artery in the first instance, or to give a freer egress to the discharge in a later stage of the case. We have given the preference to mild, simple, unirritating, and superficial dressings. We have not placed much faith in the utility of enveloping the parts in a tight bandage; but, after applying the first superficial dressings, have usually covered the limb with linen, wet with the lotio plumbi acetatis, or cold water. Whenever a roller was used, it was not with a view of making pressure, but of retaining the dressings. The wound having been dressed, we have then usually put in practice all such means as are generally deemed most efficient in preventing and diminishing inflammation; such as venesection, the exhibition of aperient and saline medicines, low diet, &c. When the pain was very severe in the beginning, we have prescribed opiates, and on the access of much swelling, have always been careful to let the bandage be slack. We believe that, on the whole, the application of superficial dressings and cold washes is mostly the best practice for the first twenty-four hours after the receipt of a punctured wound. But if after this period the pain should appear to increase, and the swelling to become more and more considerable, the surgeon may then remove the bandages, and apply from six to a dozen leeches to the neighbourhood of the wound. He must also substitute for the cold lotion the use of fomentations, and emollient poultices, under which is to be laid over the orifice of the wound a small pledget of spermaceti cerate, or other simple ointment. The poultices and fomentations are to be renewed morning and evening, and the leeches may be repeated, if necessary, three or four times.

By pursuing this antiphlogistic sort of treatment, suppuration may be sometimes entirely prevented, and the formation of large deep abscesses frequently averted. Should extensive collections of matter, however, take place, proper openings are to be then made without delay, either by dilating the original wound, or by making one or more incisions in other places, as may seem most advantageous. The case, in fact, is then to be treated upon the very same principles which are observed in the management of abscesses in general.

Of contused and lacerated Wounds.—The instruments which have the effect of producing what is termed a *contusion*, are either of an ordinary description, such as a cudgel, a stone, &c. or they consist of balls, bullets, and other metallic bodies, which are impelled into the flesh with immense velocity by the explosion of gunpowder. The latter occasion particular kinds of injury, well known by the name of *gun-shot wounds*, which are a class of cases so highly interesting, that although they are strictly only examples of severely contused wounds, surgeons have always found it expedient to treat of them as distinct and peculiar cases. Indeed, when it is recollected how many difficult, intricate, and momentous questions the subject of gun-shot wounds embraces, the necessity of considering it by itself is immediately manifest.

The blunt weapons, or obtuse hard substances, which, being applied with violence to any part of the living body, bruise, rupture, and otherwise hurt the fibres and vessels, may produce two different species of injury. First, they may more or less forcibly compress and crush the parts upon

WOUNDS.

upon which they act, so as to disorder the texture of those organs which are situated under the integuments, without, however, causing any breach of continuity in the skin itself. (This is the case which is usually called a *bruise*, or *contusion*.) Secondly, acting with a certain degree of violence upon the same parts, they may produce a solution of continuity which is named a *contused wound*. The latter effect more commonly follows when the surface of the contusing weapon or body is not very broad. The cases which rank as simple bruises have been described in another volume of this publication, (see *CONTUSION*,) and therefore we shall not detain the reader with any observations upon them in the present place.

The majority of wounds are attended with some degree of contusion. Those which are inflicted by the blunt edge of a sabre, or by the obtuse point of a bayonet or foil, are as much contused wounds as they are punctured ones; and hence, like other contused wounds, they do not often admit of being united by the first intention.

It must be confessed, indeed, that most of the endeavours to re-unite the sides of a contused wound, however skilfully directed, generally fail. An agglutination of the parts at most only takes place at the bottom of the wound, in which situation the flesh has suffered less contusion, the violence having spent itself, as it were, upon those parts upon which it first operated: hence suppuration of the external portion of the wound is mostly unavoidable. Still the attempt at re-union ought to be made; for if only the bottom of the wound should heal by the first intention, it will be a great advantage gained, more especially when the surface of a bone has been exposed and uncovered by the injury. However, in bringing the sides of contused wounds nearer together, the surgeon is not to attempt to do it with the same closeness and accuracy as in the instance of an incised wound. The injured parts would not bear the pressure, and the means requisite for this purpose; and it may be laid down as an established rule that nothing is more hurtful in cases of contused wounds than much pressure, either from strips of adhesive plaster, or a tight roller. Sutures in these cases are also totally unjustifiable; and we think we have seen several examples, in which a rash determination of the surgeon to close large contused wounds by stitches, tight strips of plaster, and bandages, has had no inconsiderable share in bringing on the rapid and fatal gangrene which carried off the patients. When we say, therefore, that a contused wound ought to be closed, and that its opposite surfaces should be brought nearer to each other, in order that the chance of some part of the injury uniting by the first intention may be taken, we do not mean to recommend dragging the parts together by main force, or placing them in a state of constriction. On the contrary, we think that they ought to be left quite unconfined, the adhesive plaster being used very sparingly, with considerable spaces between the strips, and so put on as rather to hold the loose parts together than to press and draw them into contact with each other. The wound then is not to be entirely covered with sticking-plaster, a practice which is hurtful even in incised wounds, but merely a strip applied at particular points, where the application promises to have great effect in hindering the wound from gaping, without producing any dangerous constriction of the parts. That a strip of adhesive plaster may frequently be used with striking advantage in contused and lacerated wounds experience daily proves; and the benefit must surprise us, when we remember that by preventing the wound from gaping in the manner it would otherwise do, we not only afford an opportunity for parts of it to re-unite, but at once diminish an inevitable cause of inflammation and suppuration, *viz.* the exposure of a large raw surface to the air.

Contused and lacerated wounds not only differ from incised wounds in the circumstance of their being more disposed to suppurate, and more difficult to heal by the first intention, they differ also in the particularity of not bleeding much, sometimes even when the largest arteries are lacerated, as must be the case when whole limbs are torn away, in consequence of becoming entangled in different kinds of machinery.

This indisposition to hemorrhage is not altogether a favourable omen, because though the patient runs less chance of bleeding to death in these cases than in cut wounds, yet the very circumstance of the large vessels not pouring out blood evinces that the violence, contusion, and other injury done to the parts, in addition to the mere division of them, must have been excessively severe, and that the dangers of the subsequent inflammation, suppuration, and sloughing of the parts, more than counterbalance the present security from bleeding.

We shall not find, in all the records of surgery, any facts more extraordinary than those which have been published at different periods on the subject of whole limbs being torn away, not only without hemorrhage, but without any other fatal effects. The cases of limbs torn off related by Cheselden, in the *Philosophical Transactions*, by La Motte, in his *Traité des Accouchemens*, by Mr. Carmichael, in the fifth volume of the *Edinb. Med. Commentaries*, and others in the second volume of the *Mém. de l'Acad. de Chirurgie*, are some of the most remarkable.

As far as our observations extend, all lacerated and contused wounds should be treated according to common antiphlogistic principles. When the injury is extensive, and attended with a great deal of contusion, venesection is to be practised, and the oozing of blood from the surface of the wound may be encouraged by the use of fomentations. With respect to dressings, they should always be of a mild un-irritating quality. After lessening, by a strip or two of adhesive plaster, the exposed cavity of the wound, when this is large and the surrounding skin loose, the part may be covered with pledgets of the unguentum cereæ, over which should be laid an emollient poultice. As the first dressings should not be removed for at least 24 or 36 hours, care ought to be taken to put into the poultice a sufficient quantity of sweet oil, to prevent it from becoming soon hard. Afterwards, however, the dressings may be changed once, twice, and even thrice a day, in bad cases, with advantage; for as soon as the sloughs begin to separate, and suppuration to take place, the necessity for changing the dressings and poultices more frequently is self-evident. In severe cases, fomentations may be used at the periods of dressing; and it will be found that nothing is so effectual in relieving the pain arising from the inflammation which has been induced. The employment of leeches also should not be forgotten, as a valuable means of palliating the inflammatory symptoms. Professor Asalini, of Milan, has lately written strongly in praise of the good effects which are produced by the application of cold washes to parts which have received contused wounds (see his *Manuale di Chirurgia*); and we believe the plan is particularly useful in the first instance, when it is a great object to check the increase of extravasated fluids in the surrounding parts. But afterwards we think emollient applications are the best; and, indeed, it may be questioned, whether the employment of cold lotions at first would not sometimes be objectionable, inasmuch as they must tend to stop the oozing of blood from the surface of the wound; a thing which is considered by many surgeons extremely beneficial, and an object which they think ought to be promoted even by the use of fomentations.

ations. This is a point, however, which comparative and unprejudiced experience is alone capable of deciding. If, in cases of lacerated and contused wounds, the surgeon is less frequently, than in incised wounds, called upon to take measures for stopping bleeding immediately after the accident, he finds greater occasion for attending to another important duty, imposed upon him in his professional attendance upon wounded persons in general: we allude to the early removal of all foreign bodies and extraneous substances from the wound. Cuts are usually made with clean sharp instruments; but contused and lacerated wounds often occur in a manner which renders them particularly likely to contain dirt, gravel, bits of glass, porcelain, &c. We have seen one case in which the patient could not use his arm for a twelvemonth, in consequence of some fragments of a broken bottle not having been taken out of a wound of the hand in the first instance. The wound did indeed heal up; but the pieces of glass occasioned so much pain and inconvenience, that the part could not be used. New incisions were unsuccessfully made for their removal, and the fingers were becoming permanently bent and contracted when we last saw the patient. Whether the foreign bodies have been subsequently extracted we know not; but the case deeply impressed us with the importance of always removing extraneous substances while a wound is fresh, and best admits of the requisite examination.

With regard to lacerated wounds, the same practical remarks apply to them which have been offered on the subject of contused wounds; but the prognosis is generally considered as more unfavourable, and in warm climates tetanus is alleged to be a very frequent consequence of these injuries. See TETANUS.

The bites of rabid animals afford examples of a most dangerous description of lacerated and contused wounds, the peril, however, originating not from the mechanical injury itself, but from the case being complicated with the insertion into the wounded part of a poison or virus, the effects of which, when they do occur, almost bid defiance to the power of the medical art. See HYDROPHOBIA.

As soon as the surface of a contused or lacerated wound has thrown off its sloughs, suppurated, became clean, and evinced a tendency to form granulations, the poultices are to be discontinued, and simple dressings employed. These are afterwards to have their quality altered, according to the appearances which the fore may assume; but any further directions respecting the management of the case, after it has arrived at this stage, must be quite superfluous here, as ample instructions will be found in the article ULCER.

Some contused and lacerated wounds would inevitably be followed by the rapid mortification of the limb, and the patient run the greatest risk of losing his life, were amputation not to be performed immediately after the receipt of the injury. These are generally examples in which the soft parts are extensively and deeply wounded, and large blood-vessels and nerves also injured. The size, however, of the wound seems of itself sometimes to be a cause of gangrene; for we remember a brewer's servant, who, when sitting on the fore-part of a dray-cart, met with an injury, by which the skin covering the front of the tibia was torn from the knee to the ankle, and though no other mischief appeared to have been received, the whole limb and even the scrotum rapidly mortified, and the man lost his life. It should be known, that these are cases of what M. Larrey calls traumatic gangrene, in which he and some other modern surgeons conceive that amputation may often be

done with success, though the mortification has not ceased to spread at the time of the operation. (See SURGERY.) This practice had also its advocates in former days; but since the time of Mr. S. Sharp and Mr. Pott, the rule of never attempting amputation before a line of separation has formed between the dead and living parts, has been acknowledged, taught, and respected, in every school of surgery. For an account of the treatment of contused and lacerated wounds which have ended in mortification, the reader must turn to the article GANGRENE.

Of Gun-shot Wounds.—Strictly these cases ought, perhaps, to be classed with other wounds, attended with much contusion and laceration of the parts; but the injuries which are received in modern warfare from the employment of fire-arms are so numerous, complicated, and various, that the subject undoubtedly merits separate consideration. A general description of these accidents, and of the method of treatment, will be found under the head of GUN-SHOT Wounds. Since that article was written, however, so much valuable information has been laid before the public by several distinguished army and navy surgeons, that it becomes necessary for us to avail ourselves of the present opportunity to notice some practical points of the first-rate importance in military surgery.

Amongst the observations on the subject of *Gun-shot Wounds* in a former volume, the reader will find a statement of some of the sentiments which were entertained by the late Mr. Hunter concerning the treatment of these injuries. It will there be found, that this celebrated surgeon, as well as a few other eminent practitioners, was far from being an advocate for immediate amputation, even in cases in which he acknowledged that there was no possibility of ultimately saving the injured limb. It was his opinion, that more patients died when the operation was done early, than when it was performed in a later stage, after inflammation had subsided, and suppuration had been fairly established. Such precepts, however, do not coincide with the results of modern experience; and, as in numerous instances, the decision for amputation or for delay involves the question of life or death, we think that every opportunity ought to be taken of refuting this part of Mr. Hunter's writings.

According to the united observations of all well-informed experienced army surgeons, it may now be set down as an established rule in military surgery, *that in every case in which a limb is so shattered and injured, that no probability of its being finally saved presents itself, amputation ought to be done at once, without any delay.* For nearly the last two hundred years, there have always been some men of talents and experience, who not only recommended, but actually adopted this judicious practice. Du Chesne, who wrote in 1625, advises the performance of amputation in cases of severe injuries of the limbs; and it is worthy of remark, that *he directs the operation to be performed before inflammation and other constitutional symptoms have supervened.* (See *Traité de la Cure générale et particulière des Arceufades*, Paris, 1625, p. 143.) Wiseman, the father of English surgery, not only recommended and practised immediate amputation, but the same thing was not infrequently done by the military surgeons of his time. (*Chirurgical Treatises* by R. Wiseman, 3d edit. London, 1696, p. 410.) The celebrated Le Dran, in his excellent little manual of military surgery, declared himself an advocate for *immediate* amputation in all cases in which that operation from the first appears to be indispensable. (See *Traité ou Réflexions tirées de la Pratique sur les Plaies d'Armes à feu*, Paris, 1737.) Ranby, who was serjeant-surgeon to king George II., entertained opinions similar to those of Le Dran, with regard to

to the advantages and necessity of immediate amputation, whenever the injury is such as to remove all reasonable hope of ultimately saving the limb. See Ranby's Method of treating Gun-shot Wounds, edit. 3. p. 29. London, 1781.

The following account of this interesting subject is principally abstracted from the third edition of Cooper's Dictionary of Practical Surgery, published in the year 1818:— After the battle of Fontenoy, in the year 1756, the Royal Academy of Surgery in France offered a prize for the best dissertation on the gun-shot injuries requiring immediate amputation, and on other cases of the same nature, where the operation, though deemed inevitable, might be delayed. The prize was adjudged to the dissertation of M. Faure, the main object of whose paper was to recommend delaying the operation. The side of the question espoused by M. Faure has found some modern advocates of distinguished talents and celebrity. Suffice it to mention the names of Hunter, Baron Percy, and Lombard. It is, however, only justice to M. Faure to state in this place, that though he regarded immediate amputation as full of danger, he admitted that there were several kinds of injuries of the extremities in which it was indispensably and immediately required. "The enumeration," says Dr. Thomson, "which this author has given of these injuries is more full and distinct than any which had been published before his time; and, what may appear singular, it does not differ in any essential respect from the enumerations given by later writers, who in combating his opinions have represented him as an enemy to amputation in almost all injuries of the extremities." See Report of Observations made in the Military Hospitals in Belgium, p. 169.

Although in France the academy of surgery thought proper to decree the prize to M. Faure, whose doctrine thus received the highest approbation, yet in that country very opposite tenets were set up by some men of distinguished talents and extensive military practice. Thus Le Dran, consulting surgeon to the French army, in his work on gun-shot wounds, published in 1737, expressly states, "that when the amputation of a limb is indispensably necessary in the case of a gun-shot wound, it ought to be done without delay." (Aphorism 9.) M. La Martinière, in particular, wrote some excellent arguments in reply to M. Bilguer; arguments which would do honour to the most accomplished surgeon of the age in which we live. (See Mémoire sur le traitement des plaies d'armes à feu, in Mém. de l'Acad. de Chirurgie, tom. xi. p. 1. edit. in 12mo.) M. Boucher, of Lille, was an advocate for the same side of the question. (See Obs. sur des plaies d'armes à feu, &c. in Mém. de l'Acad. de Chirurgie, tom. v. p. 279, &c. edit. in 12mo.) Schmucker, who was many years surgeon-general to the Prussian armies, published in 1776 an essay on amputation, in which he particularly mentions, that during his stay at Paris in 1738, the surgeons of the Hôtel-Dieu had been in the habit of performing immediate amputation in severe injuries of the extremities. He also declares himself an advocate for operating immediately, in all cases in which amputation from the first appears to be necessary, and insists, in a particular manner, on the increased danger which he had seen arise from the operation during the second period. He gives, as Dr. J. Thomson has observed, a minute and circumstantial enumeration of those injuries, both of the upper and lower extremities, in which he conceived amputation to be necessary, and in many of which he had actually performed it with great success. Schmucker appears to Dr. Thomson to have given a better account than any preceding military surgeon of the injuries of the

thigh; and from the results of his experience, he was led to believe, that *though compound fractures of the lower part of the thigh-bone might, in favourable circumstances, be cured without amputation, yet that this operation is peculiarly necessary in all cases in which the fracture is situated in or above the middle of that bone.* (See *Untersuchung über die Abnehmung der Glieder* von J. L. Schmucker. *Vermischte Chirurgische Schriften*, band i. Berlin, 1785.) With the foregoing high authority we have to join one of not less celebrity, namely, that of M. Larrey, who has proved most convincingly, that when amputation is to be done in cases of gun-shot wounds, nothing is so pernicious as delay. See *Mémoires de Chirurgie Militaire*, tom. ii. p. 451, &c.

The principles inculcated by M. Larrey are, in point of fact, the same as those which were so strenuously insisted upon by Mr. Pott, in his remarks on amputation. Mr. Pott, indeed, was not an army surgeon, and what he says was not particularly designed to apply to military practice, but he has represented, as well as any body can do, the propriety of immediate amputation for injuries, which leave no doubt that such operation cannot be dispensed with.

Mr. John Bell, amongst the moderns, also defended the propriety of early amputation, long before the sentiments of later writers were ever heard of. He distinctly states, that "amputation should, in those cases where the limb is plainly and irrecoverably disordered, be performed upon the spot." (See *Discourses on the Nature, &c. of Wounds*, p. 488. edit. 3.) Indeed, notwithstanding all the modern pretensions to novelty upon this interesting topic, we must acknowledge, with Dr. Thomson, that the evidence in favour of the advantages of immediate amputation has always preponderated over that for delay. See Report of Obs. made in the Military Hospitals in Belgium, p. 225.

The strongest body of evidence upon this matter, however, is adduced by M. Larrey, whose situation at the head of the medical department of the French armies has afforded him most numerous opportunities of judging from actual experience.

"If we are to be told," says he, "that the amputation of a limb is a cruel operation, dangerous in its consequences, and always grievous for the patient, who is thereby mutilated; that, consequently, there is more honour in saving a limb, than in cutting it off with dexterity and success; these arguments may be refuted by answering, that amputation is an operation of necessity, which offers a chance of preservation to the unfortunate, whose death appears certain under any other treatment; and that if any doubt should exist of amputation being absolutely indispensable to the patient's safety, the operation is to be deferred, till nature has declared herself and given a positive indication for it. We are also justified in adding, that this chance of preservation is at the present day much greater than at the epoch of the academy of surgery. We learn from M. Faure, that of about three hundred amputations performed after the battle of Fontenoy, only thirty were followed by success, whilst, on the contrary, says M. Larrey, we have saved more than three-fourths of the patients on whom amputation has been done, and some of whom also had two limbs removed. This improvement is ascribed by M. Larrey, 1st, to our now knowing better how to take advantage of the indication and favourable time for amputating; 2dly, to the dressings being more methodical; 3dly, to the mode of operating being more simple, less painful, and more expeditious, than that formerly in vogue."

To the preceding authorities against delaying amputation, in cases of gun-shot wounds requiring such operation, we have to add that of Mr. Guthrie, deputy inspector of military

tary hospitals, whose opportunities of observation, during the late war in Spain, were particularly extensive. Mr. Guthrie, however, does not recommend amputation to be done immediately, if the patient be particularly depressed by the shock of the injury directly after its receipt. "If a soldier, at the end of two, four, or six hours after the injury, has recovered from the general constitutional alarm occasioned by the blow, his pulse becomes regular and good, his stomach easy, he is less agitated, his countenance revives, and he begins to feel pain, stiffness, and uneasiness in the part: he will now undergo the operation with the greatest advantage, and if he bears it well, of which there will be little doubt, he will recover in the proportion of nine cases out of ten, in any operation on the upper extremity, or below the middle of the thigh, &c. If, on the contrary, the operation be performed before the constitution has recovered itself, to a certain degree, from the alarm it has sustained, the additional injury will most probably be more than he can bear, and he will gradually sink under it and die." (On Gun-shot Wounds, p. 24. London, 1815.) As far as our experience goes, however, all delay is improper when the necessity of amputation is undoubted, at least all delay beyond the short period, during which the faintness immediately arising from the injury usually lasts. In the campaign in Holland, in 1814, the most successful amputations were those done in the field hospitals directly after the arrival of the patients. On this point, however, hardly any difference of sentiment prevails, because all naval and military surgeons agree, and mean, that amputation is not to be performed till the faintness and depression of the powers of life, directly following the wound, have been sufficiently obviated for the patient to bear the operation well. The seeming difference, therefore, on this matter, between Mr. Guthrie and Mr. Hutchison, is not very material. (See Hutchison's Practical Obs. on Surgery, 1817.) It appears from some returns, collected by Mr. Guthrie, that in the peninsula, the comparative loss, in secondary or delayed operations, and in primary or immediate amputations, was as follow:

	Secondary.	Primary.
Upper extremities	- - 12 to	1
Lower extremities	- - 3 to	1

The great success attending amputation on the field of battle was also convincingly proved after the battle of Toulouse. Here of 47 immediate amputations, 38 were cured, while of the 51 delayed operations, on that occasion, 21 had fatal terminations. P. 42—44.

Lastly, we have to notice, amongst the advocates for immediate amputation, Mr. Hennen, a surgeon employed with our army in Spain and the Netherlands. "The question," says he, "of immediate amputation has of late attracted an attention, which its great importance naturally calls forth; but it appears to me, that an idea has been impressed upon the minds of practitioners in civil life, that doubts as to the propriety of the practice had existed among the British army surgeons. For my own part, I have never known any differences of opinion on the point. In books, it is true, it has been most amply discussed before the present generation were in existence; but in British practice all doubts have long been at an end. It is but justice to British surgeons, both naval and military, to declare, that immediate amputation is neither a new doctrine nor a recent practice among them, &c." See Hennen's Obs. on some important Points in the Practice of Military Surgery, p. 45. Edinb. 1818.

If, however, military surgeons have definitively settled

the great question, that in all cases in which a limb cannot be saved, the sooner amputation is done the better, they neither have, nor probably will ever be able positively to settle and define the exact degrees of injury which, in every instance, ought to be followed by putting the former rule in practice. In fact, no part of surgery is more difficult, than that in which the question of the possibility or impossibility of saving wounded limbs is submitted to the judgment and determination of the practitioner. Some injuries, indeed, are so bad, that no difficulty in making a decision is experienced; but there are other cases, in which the damage done to the parts is less violent and extensive, and in which the exact degree of mischief is not at first apparent. There are, in short, numerous doubtful examples, in which the formation of a right judgment is equally difficult and important.

The annexed remarks will convey the sentiments of some of the latest writers on the second great question in military surgery. What are the exact cases in which amputation should be done immediately, and what are those in which the operation may be deferred?

Of Cases in which Amputation should be done immediately.—First case. A limb carried away by a cannon-ball, or the explosion of a howitzer, or bomb, requires amputation without any loss of time: the least delay puts the patient's life in danger.

In this case, the necessity of the practice is inculcated by M. Faure himself, as well as by Schmucker, Richter, Larrey, Dr. Thomson, and every modern writer upon gun-shot wounds.

If the operation be not speedily done, pain commences, fever occurs, and the functions become disordered; the irritation then increases, and convulsive motions take place. If the patient should not be a victim to these first symptoms (continues Larrey), gangrene of the stump is occasioned, the fatal consequences of which it is extremely difficult to prevent.

Second case. When a body propelled by gunpowder strikes a limb, in such a manner as to smash the bones, violently contuse, lacerate, and deeply tear away the soft parts, amputation ought to be immediately performed. If this measure be neglected, all the injured parts will soon be seized with gangrene: and besides, as M. Larrey has explained, the accidents which the gravity of the first case produces will also here be excited. It is only doing justice to the memory of M. Faure to state, that this second case was one which he also particularly intimated as demanding the immediate performance of amputation. See Prix de l'Acad. Royale de Chirurgie, tom. viii. p. 23. edit. 12mo.

Third case. If a similar body were to carry away a great mass of the soft parts, and the principal vessels of a limb (of the thigh for instance), without fracturing the bone, the patient would be in a state demanding immediate amputation; for, independently of the accidents which would originate from a considerable loss of substance, the limb must inevitably mortify. Mr. Guthrie also says, "a cannon-shot destroying the artery and vein on the inside (of the thigh), without injuring the bone, requires amputation." (P. 185.) When, however, the femoral artery or vein is injured by a musket-ball, or small cannister-shot, this gentleman recommends tying the vessel above and below the wound in it, if the nature of the case be evinced by hemorrhage. But he believes, that when both vein and artery are injured, amputation is necessary. (P. 186.) An injury of the femoral artery, observes Mr. Guthrie, requiring an operation, and accompanied with fracture of the bone of the most simple kind, is a proper case for immediate amputation.

tion; for although many patients would recover from either accident alone, none would surmount the two united, and the higher the accident is in the thigh, the more imperious is the necessity for amputation.

Fourth case. A large biscayen strikes the thick part of a member, breaks the bone, divides and tears the muscles, and destroys the large nerves, without, however, touching the main artery. According to M. Larrey, this is a fourth case requiring immediate amputation.

Mr. Guthrie also says, that "if a cannon-shot strike the back part of the thigh, and carry away the muscular part behind, and with it the great sciatic nerve, amputation is necessary, even if the bone be untouched, &c. In this case, I would not perform the operation by the circular incision, but would preserve a flap from the fore part or sides, as I could get it, to cover the bone which should be short." Guthrie on Gun-shot Wounds of the Extremities, p. 184.

Fifth case. If a spent cannon-shot, or one that has been reflected, should strike a member obliquely, without producing a solution of continuity in the skin, as often happens, the parts which resist its action, such as the bones, muscles, tendons, aponeuroses, and vessels, may be ruptured and lacerated. The extent of the internal disorder is to be examined; and if the bones should feel through the soft parts as if they were smashed, and if there should be reason to suspect from the swelling, and a sort of fluctuation, that the vessels are lacerated, amputation ought to be immediately practised. We learn from M. Larrey, that this is also the advice of M. Percy, an eminent French army surgeon. Sometimes, however, the vessels and bones have escaped injury, and the muscles are almost the only parts disordered. In this circumstance, we are enjoined to follow the council of M. La Martinière, who recommended making an incision through the skin. By this means, a quantity of thick blackish blood will be discharged, and the practitioner must await events. According to M. Larrey, such incision is equally necessary in the preceding case before amputation, in order to ascertain the extent of the mischief which the parts have sustained.

It is to such injury done to internal organs, that we must ascribe the death of many individuals, which was for a long while attributed to the commotion produced by the air put in motion by the ball, when this, in grazing upon different parts of the body, alters them, or cuts off the column of air which is to serve for respiration, just at the moment when it is about to enter the chest. See Ravaton's *Traité des Plaies d'Armes à Feu*.

But to return to the object of our present consideration. M. Larrey expresses his belief, that what have been erroneously termed *wind contusions*, if they are attended with the mischief above specified, require immediate amputation. The least delay makes the patient's preservation extremely doubtful. The internal injury of the member may be ascertained by the touch, by the loss of motion, by the little sensibility retained by the parts which have been struck, and, lastly, by practising an incision, as already recommended.

Sixth case. When the articular heads are much broken, especially those which form the joints of the foot or knee, and the ligaments, which strengthen these articulations, are broken and lacerated by the fire of a howitzer or by a biscayen, or other kind of ball, immediate amputation, says M. Larrey, is indispensable. According to this experienced writer, the same indication would occur, were the ball lodged in the thickness of the articular head of a bone, or were it so engaged in the joint as not to admit of being

extracted by simple and ordinary means. (See also Guthrie on Gun-shot Wounds, p. 197.) Putting out of consideration cases in which the injury has been done by a clean cutting instrument, or in which a small ball has passed near or partially injured a joint, another experienced army surgeon also lays it down as a law in military surgery, that *no lacerated joint, particularly the knee, ankle, or elbow, should ever leave the field unamputated, where the patient is not obviously sinking, and consequently where certain death would follow the operation.* (Hennen's Military Surgery, p. 42.) And in another place he tells us: "In my own practice, I have met with only two cases, where the limb was saved after a serious injury of the knee-joint; and in one of them only was the perfect use of it restored. I never met with an instance where the ankle or elbow-joint was perfectly restored after severe injury, though some where the limb has been saved. Of the shoulder-joint the recoveries are more frequent." P. 159.

Fractures extending into the joints, and accompanied with great laceration of the ligaments, were cases of gun-shot injuries pointed out by M. Faure as indispensably requiring immediate amputation. (See *Prix de l'Acad. de Chir.* tom. viii.) Thus we see, that this author was not so averse to early amputation as several modern writers have represented.

It is only in this manner, that the patients can be rescued from the dreadful pain, the spasmodic affections, the violent convulsions, the acute fever, the considerable tension, and the general inflammation of the limb, which, M. Larrey observes, are the invariable consequences of bad fractures of the large joints. But, adds this author, if the voice of experience be not listened to, and amputation be deferred, the parts become disorganized, and the patient's life is put into imminent peril.

It is evident, says he, that, in this case, if we wish to prevent the patient from dying of the consequent accidents, amputation should be performed before twelve or at most twenty-four hours have elapsed: even M. Faure himself professed this opinion, in regard to certain descriptions of injury. *Mém. de Chir. Militaire*, tom. ii.

With respect to wounds of the knee, the sentiments of Mr. Guthrie nearly coincide with those of M. Larrey. "I most solemnly protest (says Mr. G.) I do not remember a case do well, in which I knew the articulating end of the femur, or tibia, to be fractured by a ball that passed through the joint, although I have tried great numbers, even to the last battle of Toulouse. I know that persons wounded in this way have lived; for a recovery it cannot be called, where the limb is useless, bent backward, and a constant source of irritation and distress, after several months of acute suffering, to obtain even this partial security from impending death; but if one case of recovery should take place in fifty, is it any sort of equivalent for the sacrifice of the other forty-nine? Or is the preserving of a limb of this kind an equivalent for the loss of one man?" On Gun-shot Wounds, p. 196.

Mr. Guthrie admits, that fractures of the patella, without injury of the other bones, admit of delay, provided the bone is not much splintered.

Seventh case. According to M. Larrey, if a large biscayen, a small cannon-shot, or a piece of a bomb-shell, in passing through the substance of a member, should have extensively denuded the bone, without breaking it, amputation is equally indicated, although the soft parts may not appear to have particularly suffered. Indeed, the violent concussion produced by the accident has shaken and disorganized all the parts; the medullary substance is injured, the vessels

are lacerated, the nerves immoderately stretched, and thrown into a state of stupor; the muscles are deprived of their tone; and the circulation and sensibility in the limb are obstructed. Before deciding, however, M. Larrey cautions us to observe attentively the symptoms which characterize this kind of disorder. This case can be supposed to happen only in the leg, where the bone is very superficial, and merely covered at its anterior part with the skin.

The following are described as the symptoms: the limb is insensible, the foot cold as ice, the bone partly exposed, and on careful examination, it will be found that the integuments, and even the periosteum, are extensively detached from it. The commotion extends to a considerable distance; the functions of the body are disordered; and all the secretions experience a more or less palpable disturbance. The intellectual faculties are suspended, and the circulation is retarded. The pulse is small and concentrated, the countenance pale, and the eyes have a dull moist appearance. The patient feels such anxiety, that he cannot long remain in one posture, and requests that his leg may be quickly taken off, as it incommodes him severely, and he experiences very acute pain in the knee. When all these characteristic symptoms are conjoined, says M. Larrey, we should not hesitate to amputate immediately; for the leg would be attacked with sphacelus the same day, and the patient would certainly perish.

M. Larrey next adduces several interesting cases in support of the preceding observations.

Eighth case. When a large ginglymoid articulation, such as the elbow, or especially the knee, has been extensively opened with a cutting instrument, and blood is extravasated in the joint, M. Larrey deems immediate amputation necessary. In these cases, the synovial membranes, the ligaments, and aponeuroses, inflame, the part swells, and erethism rapidly takes place; and acute pains, abscesses, deep sinuses, caries, febrile symptoms, and death, are the speedy consequences. M. Larrey has seen numerous subjects die of such injuries, on account of the operation having been postponed with a hope of saving the limb. In his *Mémoires de Chirurgie Militaire*, tom. ii. some of these are detailed.

Although a wound may penetrate a joint, yet if it be small and unattended with extravasation of blood, M. Larrey informs us, it will generally heal, provided too much compression be not employed. This gentleman believes in the common doctrine of the pernicious effect of the air on the cavities of the body; yet, in this place, a doubt seems to affect him: speaking of the less danger of small wounds of joints, he says, "a quoi tient cette différence, puisque l'air pénètre dans l'articulation dans l'un comme dans l'autre cas?"

When two limbs have been at the same time so injured as to require amputation, we should not be afraid of amputating them both immediately, without any interval. We have, says M. Larrey, several times performed this double amputation with almost as much success as the amputation of a single member. He has recorded an excellent case in confirmation of this statement. *Mém. de Chirurgie Militaire*, tom. ii. p. 478.

When a limb is differently injured at the same time in two places, and one of the wounds requires amputation, (suppose a wound of the leg with a splintered fracture of the bone, and a second of the thigh, done with a ball, but without any fracture of the os femoris, or other bad accident,) M. Larrey recommends us, first to dress the simple wound of the thigh, and amputate the leg immediately afterwards, if the knee be free from injury. When it is necessary to

amputate above this joint, the less important wound need not be dressed till after the operation, provided it can be comprehended in the section of the member, or be so near the place of the incision as to alter the indication. When the wound demanding amputation is the upper one, the operation of course is to be done above it, without paying any regard to the injury situated lower down.

M. Larrey, however, approves of deferring the operation, when delirium, convulsions, and inflammation, prevail on the first receipt of the injury. In this circumstance, we are advised to take measures for appeasing these accidents; the progress of nature is to be carefully observed; and the first moment of quiet is to be taken advantage of for the performance of the operation. See Larrey's *Mém. de Chirurgie Militaire*, tom. ii. p. 451, &c.

Ninth case. To the foregoing species of gun-shot wounds, pointed out by M. Larrey as urgently requiring immediate amputation, are to be added compound fractures of the thigh from gun-shot violence.

"Gun-shot fractures of the thigh," says Dr. J. Thomson, "have been universally allowed to be attended with a high degree of danger; indeed, till of late years, very few instances have been recorded of recovery from these injuries. Ravaton acknowledges, that in his long and extensive experience, he had never seen an example of recovery from a gun-shot fracture of the thigh; and Bilguer, in his calculations with regard to those who recover from gun-shot fractures, sets aside those of the thigh-bone, as being of a nature altogether hopeless. In the present improved state of military surgery, instances not unfrequently occur of recovery from this fracture; but of these, the number will be found, I believe, to be exceedingly small, in comparison with those who die, particularly when the fracture has had its seat above the middle of the bone, &c."

According to the observation of Percy, scarcely two of ten recover of those who have suffered gun-shot fractures of the thigh-bone. Mr. Guthrie says, that "upon a review of the many cases which I have seen, I do not believe that more than one-sixth recovered so as to have useful limbs; two-thirds of the whole died either with or without amputation; and the limbs of the remaining sixth were not only nearly useless, but a cause of much uneasiness to them for the remainder of their lives." See Guthrie on Gun-shot Wounds, p. 191.

"In fractures by musket-bullets of the lower part of the thigh-bone (says Dr. Thomson), recovery not unfrequently takes place; and both Schmucker and Mr. Guthrie conceive, that they are injuries in which amputation may be delayed with safety. It would be very agreeable, that this opinion should be confirmed by future experience; but it appears to me, that before it can be received as a maxim in military surgery, much more extensive and accurate observation than we yet possess will be required, with regard to the proportion of those who recover without amputation, or after secondary operations, and of those who recover after primary amputation. Of those who had suffered this injury, we saw, comparatively, but a small number recovering in Belgium, and they had been attended with severe local and constitutional symptoms." See Report of Observations made in the Military Hospitals in Belgium, p. 247, *et seq.*

Balls often produce fissures of several inches in length in the thigh-bone. This is a state, observes Dr. Thomson, which must be very unfavourable to recovery; and his conclusion is, that in general, even in fractures of the lower part of the thigh-bone, a greater number of lives will be preserved in military practice by immediate amputation,

than by attempting the cure without that operation. "When the bone appears, on a careful examination, to be broken without being much splintered, and when the patient can be removed easily to a place of rest and safety, it may be right to attempt to preserve the limb; but if the bone be much splintered, or if the conveyance is to be long or uncertain, it will, in most instances, I am convinced, be a much safer practice, even in fractures of this part of the thigh-bone, to amputate without delay.

"Musket-bullets, in passing through the femur, near to the knee-joint, produce fissures of the condyles, which generally communicate with the joint. These cases, like those in which the bullets have passed directly through the joint, require immediate amputation.

"The writings of military surgeons contain but few histories of cases in which the thigh-bone had been fractured above its middle by the passage of musket-bullets. These are cases, I believe, which have generally had a fatal termination; and the danger attendant upon the amputation which they require, seems long to have deterred surgeons from attempting to ascertain what advantages might be derived from the employment of that operation. Schmucker recommends and states, that he had practised with success immediate amputation in those cases, in which a sufficient space was left below the groin for the application of the tourniquet. It is curious to remark, in the history of amputation, how long surgeons were in discovering the ease and safety with which the femoral artery may be compressed by the fingers, or pads, in its passage over the brim of the pelvis. Boy, from the immediate danger, protracted suffering, and ultimate want of success, which he had observed to follow this kind of injury, urges strenuously the propriety of immediate amputation: Mr. Guthrie's opinion, with regard to the dangerous nature of these injuries, and the advantages to be derived in them from immediate amputation, coincides in every respect with those of Schmucker and Boy. He observes, that those whose thigh-bone has been fractured in its upper part by a musket-bullet, generally die with great suffering before the end of the sixth or eighth week; and that few even of those escape, in whom that bone has been fractured in its middle part. Of the few whom we saw, who had survived gun-shot fractures in the upper part of the thigh-bone in Belgium, scarcely any one could be said to be in a favourable condition. In all, the limbs were much contracted, distorted, and swollen, and abscesses had formed round and in the neighbourhood of the fractured extremities of the bones. In some instances, these abscesses had extended down the thigh; but more frequently they passed upwards, and occupied the region of the hip-joint and buttocks. In several instances in which incisions had been made for the evacuation of matter, the fractured and exfoliating extremities of the bones sometimes comminuted, and sometimes forming the whole cylinder, could be felt bare, rough, and extensively separated from the soft parts which surrounded them. In other instances, these extremities were partially inclosed in depositions of new bone, which, from the quantity thrown out, seemed to be present in a morbid degree. It was obvious, that in all of these cases, several months would be required for the re-union of the fractured extremities; that in some much pain and misery were still to be endured from the processes of suppuration, ulceration, exfoliation, and ejection of dead bone; that in some cases, the patients were incurring great danger from hectic fever, and from diarrhoea; and that of those in whom this might take place, there was but little probability that any would be able to use their limbs!

The sight of these cases (says Dr. Thomson) made a deep impression upon my mind, and has tended to increase my conviction, that this is, of all others, the class of injuries in which immediate amputation is most indispensably required." See Report of Observations made in the Military Hospitals in Belgium, p. 254—258.

Dr. Thomson adds, that what has been said of the danger of fractures produced by musket-bullets in the upper part of the femur is true, in a still greater degree of those which have their seat in the neck or head of that bone. In such instances, Dr. Thomson joins the generality of modern army surgeons, in strongly recommending amputation at the hip-joint.

Of Gun-shot Wounds in which Amputation may be deferred.—If, says M. Larrey, it be possible to specify the cases in which amputation ought to be immediately performed, it is impossible to determine *a priori* those which will require the operation subsequently. One gun-shot wound, for example, will be cured by ordinary treatment, while another, that is at first less severe, will afterwards render amputation indispensable, whether this be owing to the patient's bad constitution, or the febrile complaints which are induced. However this may be, the safe rule for fulfilling the indication that presents itself, is to amputate consecutively only in circumstances in which every endeavour to save the limb is manifestly in vain. Upon this point, M. Larrey's doctrine differs from that of M. Faure.

The latter practitioner admits cases, which he terms *cases of the second kind*, in which he delays amputation, not with any hope of saving the limb, but in order to let the first symptoms subside. The operation done between the fifteenth and twentieth day, appears to him less dangerous than when performed immediately after the receipt of the injury. At the above period, according to M. Faure, the commotion occasioned by the gun-shot injury is dispelled; the patient can reconcile himself to amputation, the mere mention of which fills the pusillanimous with terror in a greater or lesser degree; the debility of the individual is no objection; and it is laid down as an axiom, "that the consequences of every amputation, done in the first instance, are in general extremely dangerous." In support of this theory, M. Faure adduces ten cases of gun-shot injuries, in which, after the battle of Fontenoy, the operation was delayed, in order that it might afterwards be performed with more success; a plan which, according to the author, proved completely successful. See *Prix de l'Acad. de Chirurgie*, tom. viii. edit. in 12mo.

This division of the cases for amputation into two classes, not consistent with nature, observes M. Larrey, has been the cause of a great deal of harm. Very often the partisans of M. Faure have not dared to resort in the first instance to amputation, the dangers of which they exaggerate; while, on other occasions, they amputate consecutively, without any success.

The effects of commotion, instead of increasing, gradually diminish and disappear after the operation. It is proved, says he, that the commotion, so far from being a counter-indication to immediate amputation, is a reason that should incline the surgeon to operate. Such was the sentiment of La Martinière and Boucher.

Neither ought the patient's alarm to be a reason for postponing the operation; for according to M. Larrey, the patient just after the accident will be much less afraid of the risk which he has to encounter, than after the expiration of the first four-and-twenty hours, when he has had time to reflect upon the consequences of the injury, or of amputation. This remark has been made by the illustrious Paré.

“Experience,” says M. Larrey, “has proved, both to the army and navy surgeons, that the bad symptoms which soon follow such gun-shot injuries as must occasion the loss of a limb, are much more to be dreaded than those of immediate amputation. Out of a vast number of the wounded, who suffered amputation in the course of the first four-and-twenty hours after the memorable naval battle of the first of June, 1794, a very few lost their lives.”

M. Larrey next acquaints us, that when he was sent to the army of Italy in 1796, he had also the pain of seeing in the hospitals great numbers of the wounded fall victims to the confidence which many of the surgeons of that army placed in the principles of M. Faure. General Bonaparte saw, that the *ambulance volante* was the only thing that, in the event of fresh hostilities, could prevent such accidents; and in consequence of his orders, M. Larrey formed the three divisions d’ambulance, which are described in his *Mémoires de Chirurgie Militaire*.

Since this period, it has always been customary in the French armies, on the day of battle, to make every preparation for performing amputation as speedily as possible. The mere sight of these *ambulances*, (always attached to the advanced guard,) says M. Larrey, encourages the soldiers, and inspires them with the greatest courage.

M. Larrey desires us to interrogate the invalids who have lost one or two of their limbs, and nearly all will tell us, that they suffered amputation a few minutes after the accident, or in the first four-and-twenty hours.

“If M. Faure now retains any partisans,” says M. Larrey, “I recommend them to repair to the field of battle the day after an action; they would then soon be convinced, that without the prompt performance of amputation, great numbers of soldiers must inevitably lose their lives. In Egypt, this truth was particularly manifested.”

Admitting, says M. Larrey, that by a concurrence of fortunate circumstances, which are not always to be calculated upon, some patients escape the danger of the first symptoms, this proves nothing in favour of doing the operation afterwards: it must be seen what nature will do towards the event of the case.

If at the end of twenty or thirty days the prognostic is as bad as it was previously, amputation cannot be avoided. Thus all the sufferings which the patient has endured have been undergone for nothing, and the operation will now be attended with considerable risk, inasmuch as the patient may lie in a dangerously weakened state.

If nature revives at all, no doubt the success of the operation becomes more probable; but in this case, the surgeon, instead of having recourse to amputation, should redouble his efforts to preserve the limb.

Cases demanding Amputation consecutively.—M. Larrey gives us the annexed information upon this subject.

First case. *A spreading Mortification.*—If the disorder be owing to an internal and general cause, it would then be rashness in the surgeon to amputate before nature had put limits to the disease. This kind of gangrene, according to M. Larrey, is distinguished from that which is named *traumatic*, by the symptoms which precede and accompany it. These symptoms are similar to those which are observed in nervous ataxia, or adynamia. Here the operation ought to be deferred, and endeavours made to combat the general causes with regimen and internal medicines.

But when the gangrene is *traumatic*, the limb, says M. Larrey, should be immediately cut off above the disorganized part. Several facts in support of this advice are related by this experienced surgeon in his *Mémoire sur la Gangrene Traumatique*. See SURGERY.

How contrary this advice to that inculcated by Sharp, Pott, and nearly all eminent surgeons of the present time!

A particular case of gangrene has been pointed out by Mr. Guthrie as demanding the early performance of amputation, and a deviation from the old rule of waiting till the mortification has ceased to spread. It is when gangrene occurs after wounds of the large blood-vessels of a limb. See Guthrie on Gun-shot Wounds of the Extremities, p. 63, &c.

Second case. *Convulsions of the wounded Limb.*—Amputation of the member, performed immediately the first symptoms of tetanus manifest themselves, more especially those of chronic tetanus, was proposed and even practised by Larrey with partial success. He supposed, that all communication between the original injury, and the rest of the body being thus cut off, the general disorder might cease.

Third case. *Bad State of the Discharge.*—It often happens, that in gun-shot wounds, complicated with fractures, notwithstanding the most skilful treatment, the discharge becomes of a bad quality; the fragments of bone lie surrounded with the matter, and have not the least tendency to unite; the patient is attacked with hectic fever, and a colliquative diarrhoea. Under these circumstances, life may sometimes be preserved by amputation.

Fourth case. *Bad State of the Stump.*—In hospitals, says M. Larrey, the cure of amputations is sometimes prevented by a fever of a bad character. The stump swells, the integuments become at first retracted, and then reverted and diseased a good way upward. The wound changes into a fungous ulcer, the cicatrization of which is hindered by the deep disorder of the bone, and the ulceration of the soft parts. The extremity of the bone projects. In order to remedy this last evil, it has been proposed to saw off the projecting part of the bone, and with this even to amputate all the flesh beyond the level of the skin. M. Larrey condemns such practice, as unnecessary and dangerous, and he recommends giving nature time to effect the exfoliation of the diseased projecting part of the bone, and heal the wound.

Of poisoned Wounds.—These injuries are essentially different from every other description of wound, their great particularity depending upon the introduction of a venomous matter into the wounded parts, or its deposition upon the surface of the injury; and, in general, the poison is inserted by the weapon with which the solution of continuity is produced. Sometimes, however, the contrary happens, when previous cuts, or scratches of the fingers, which are not healed, become infected with a virus, in the dissection of bodies, or in the dressing of venereal ulcers. Nay, there has lately been recorded in the public papers a remarkable instance, in which a nobleman’s servant died, as is alleged, from the effects of the poison of a torpid viper, the fangs and poisoned apparatus of which he had been handling and exhibiting to some visitors, at a time when he happened to have a slight cut upon one of his fingers. The case is extraordinary, not only on account of the way in which the infection was contracted, but also on account of the fatal event, which is very uncommon in animals of the magnitude of the human subject, as we shall hereafter notice.

Pricks with the point of a dissecting-knife, when the instrument is covered with putrid, infectious, irritating matter, may be considered as a class of poisoned wounds. Sometimes, however, such accidents are followed by no injurious effects; and when the subject is strong and robust, a little inflamed tumour occurs in the situation of the puncture, the part festers, bursts, and then heals up. But, as Richerand observes,

observes, when the accident befalls a young man, who has been much weakened by hard study, any kind of excess, or some previous disease, it frequently happens that no local symptoms are seen. At the end of 24 or 36 hours, sometimes rather sooner, sometimes later, the axillary glands become affected with swelling, and a painful phlegmonous inflammation takes place in them. The wound afterwards festers; the parts around it exhibit appearances of a slow sort of inflammation, and the consequent swelling of the hand is rather œdematous than inflammatory. Next often succeed nausea and propensity to vomit, prostration of strength, a small accelerated pulse, and all the usual symptoms of typhus fever. Under these circumstances, if, instead of a tonic plan of treatment, which is strongly indicated, the evacuating method be adopted, the patient very soon falls a victim.

Experience fully proves, that in strong vigorous habits, nature resists with energy the introduction of poisons into the system.

In the cases under our consideration, tonic and cordial remedies are to be given in moderation. At the same time, care is to be taken to clear out the *primæ viæ*, when they appear to be disordered. Abroad, it is the common practice also to apply a grain of caustic potassa, or a drop of the liquid muriate of ammonia, to the little wound itself.

The stings of venomous insects, such as the bee, wasp, hornet, &c. are commonly treated of with poisoned wounds. The pain of the injury is alleged to depend less upon the introduction of the sting, which sometimes breaks and is left behind, than upon the insertion of a venomous fluid into the part. It is said indeed, that the experiments made by professor Dumeril prove, that when the little cyst, situated at the base of the sting, is removed, the introduction of the sting itself into the flesh causes no particular pain. At the base of the sting there is a kind of vesicle, or reservoir, for containing the poisonous secretion, which is expelled and flows out along the sting, at the instant when the latter penetrates the parts which are stung. The venom of the bee is stated to be neither of an acid nor of an alkaline nature. When applied to mucous surfaces, and even to the tunica conjunctiva of the eye, it produces no disagreeable sensation; but if the point of a needle, after being dipped in it, be introduced into the flesh, a very acute pain is immediately excited. Various kinds of oil, honey, ammonia, spirit of wine, and several other reputed specifics, appear to deserve no such character, since they are found, after unprejudiced trials, to have no power of neutralizing the venom, nor of appeasing the actual pain arising from the sting.

When, therefore, a person has been stung by one or several bees, we are recommended to begin with extracting the stings, taking care, however, previously to cut off with a pair of scissors the little vesicle at their base containing the venomous secretion. This is to be done, lest in the endeavours to remove the sting more of the venom should be compressed out of the little reservoir into the wound. The part is afterwards to be covered with snow, or bathed with ice-cold water, or some cooling sedative lotion. In short, the case is to be treated on common antiphlogistic principles, experience having fully proved that no specific has yet been discovered for the sting of the bee, and other venomous insects. For other opinions and observations on this subject, see the article BEE.

Bite of the Viper.—Of all the venomous reptiles which are met with in Europe, there are none which inflict so dangerous a bite as the viper or adder. Its upper jaw is furnished with two moveable fangs, which are very sharp-

pointed, grooved longitudinally, and at their root are connected with a vesicle which contains the venomous fluid. When the animal is irritated, the fangs become raised, and the poison flows along the grooves in them into the bitten part. The danger of the injury is in some measure proportioned to the fury of the animal; for when it is very much exasperated, it closes its jaws with greater force, and more of the venom is compressed into the wound. The degree of danger is also influenced considerably by the greater or less space of time that has elapsed since the reptile emptied the receptacles of its venom, by biting another person or animal. The injury likewise is generally found to produce less serious consequences, in proportion to the greater size of the animal which has been bitten. The experiments of Fontana prove, that the bite of a single viper will kill a mouse, a pigeon, or any other small animal; but that it must be the bites of several to kill a man, and of a still larger number to destroy an ox. It is also supposed by many writers on this subject, that in all animals, whatever may be their size, the degree of danger is considerably greater, if they should be much frightened on the occasion, the prostration of strength produced by fear being conjectured to facilitate in a peculiar manner the pernicious operation of the venom. When a dog is bitten suddenly and unexpectedly, he is, *cæteris paribus*, much less hurt than when he has received the injury in a contest with the reptile, whose very aspect has more or less alarmed him. The bite of the viper is thought to prove generally more or less severe, in proportion to the heat of the weather.

The danger of the injury depends less upon the laceration of the parts, which, however, is considerable, than upon the kind of venomous inoculation with which it is attended. The symptoms which are excited come on almost immediately. The person who has received the bite suffers acute pain, and an inflammatory swelling spreads up the limb with remarkable rapidity, accompanied with a tendency to gangrene, as is indicated by the appearance of livid spots. Affections of the heart, attended with great weakness and vertigo, denote that the action of the poison extends to the whole system. But these general effects do not arise, as Fontana wrongly imagined, from the venom having a power of coagulating the blood in the vessels, but in all probability from its operation upon the nervous system.

The best plan of counteracting the baneful effects of the bite of the viper consists in introducing a few drops of the fluid muriate of antimony into the wound, and a small hair pencil may be used for the insertion of the caustic, if the punctures should happen to be deep. Indeed, when the bottom of the wound cannot be cauterized without dilating it, the latter step is deemed proper by the generality of surgical writers. The surrounding parts may be rubbed with a liniment composed of hartshorn and olive-oil; and cordial medicines are to be exhibited, especially ammonia.

The amputation of the bitten part is rather too severe a mode of preventing the usual ill consequences of the bite of a viper to deserve recommendation. The ancients, with a view of counteracting the introduction of the poison into the body, were accustomed to apply a ligature round the limb above the injury; but it is a painful expedient, because it cannot hinder the absorption of the venom, and the general constitutional affection, unless the band be put on with sufficient tightness to impede the circulation. This, however, is the method which was adopted by Ambroise Paré, after he had been accidentally bitten by an adder.

The most important object in the treatment is the prompt application of remedies; for the introduction of the virus into

into the constitution ought to be prevented, if possible. This is more likely to be accomplished than any aim at neutralizing the venomous fluid, after its effects have extended to the whole animal economy.

Even when the bite of a viper is entirely neglected, it very rarely proves fatal to the human subject. In many cases, the patients have recovered favourably under the mere use of olive-oil and of ammonia. These two medicines have been recommended as specifics both in the Transactions of the Royal Society, and by the celebrated Bernard de Jussieu; and amongst the cases in proof of their efficacy, authors still continue to quote the example of a dealer in vipers, who was quite indifferent about being bitten by these animals. He used to bathe the part in olive-oil, and at the same time drink several ounces of this fluid. And in another instance, which is frequently cited, a student of botany, while herborizing, was bitten by a viper in a place where no medicine was at hand, except the eau de luce. Jussieu, who was present, introduced a few drops of this remedy into the wound, and administered a tea-spoonful of it internally in a glass of water. The eau de luce is nothing more than the liquor ammoniæ, containing a small quantity of the oleum succini.

In France, and in other parts of the continent, the eau de luce is still looked upon as the internal medicine, on which most reliance can be placed.

In this country, arsenic, in strong doses, has been particularly recommended for its beneficial effects in counteracting the operation of the poison of snakes. The Tanjore pill, which has long been famous in India for its virtues in preventing the fatal symptoms arising from the bites of serpents in hot countries, was known to have arsenic as one of its ingredients. Mr. Ireland, an army surgeon, happened to be at St. Lucia, in the West Indies, when several men of the 62d regiment were bitten by the coluber carinatus of Linnæus, the bite of which had already proved quickly fatal to several men of the same corps. Mr. Ireland immediately administered Fowler's solution of arsenic in strong doses, and the results of the cases, in which he had an opportunity of trying it, were highly favourable to the practice, as the men's lives were preserved by it. (See *Medico-Chir. Trans.* vol. ii. p. 393, &c.) Perhaps the prompt excision of the bitten part, or the free use of the actual cautery, should also be invariably put in practice, for the bites of the more deadly kinds of serpents, in conjunction with the exhibition of arsenic. But the ordinary consequences of the bite of a common adder are not serious enough to require so severe a proceeding as the excision or amputation of the parts would often be. Some observations on the structure of the viper will be found in the article COLUBER, and other remarks on the bite of this animal will be seen in the articles POISON and VIPER.

The worst poisoned wounds ever met with in this climate are those produced by the bite of a mad dog, and other rabid animals; but for a particular account of this highly interesting subject, we must refer to HYDROPHOBIA.

Wounds of different Parts of the Face, Eye, Eye-lids, Ears, &c.—The countenance being the part in which any deformity is peculiarly conspicuous, it is always a great desideratum, in cases of wounds of the forehead, cheeks, nose, lips, &c. to prevent as much as possible the formation of ugly scars. Hence it is an invariable maxim to endeavour to heal wounds of the face by the first intention.

As cuts of the face can hardly be very deep, adhesive plaster is generally sufficient for holding their opposite edges together; but when the wound is situated in the lips, these

parts are so incessantly in motion, that surgeons find it best to maintain the sides of the division in contact by means of the twisted suture, a description of which is given in the article HARELIP.

When the edges of a wound of the lips are much contused and lacerated, some authors recommend them to be pared off, in order to increase the chance of union, and lessen the disfigurement of an uneven cicatrix.

Punctures of the transparent cornea of the eye are in themselves much less serious accidents than similar injuries of the sclerotic coat, which are almost unavoidably combined with a wound of the choroides and retina. Hence, the latter cases are frequently followed by a considerable degree of inflammation. Sometimes the crystalline lens itself is injured, and afterwards grows opaque.

Incisions made in the transparent cornea with very sharp instruments may not give rise to any serious consequences; and notwithstanding the escape of the aqueous humour, the crystalline lens and vitreous humour may remain in their natural situation. The form, thickness, and density of the cornea are circumstances which produce a spontaneous approximation of the edges of the wound to each other, and which, in fact, are extensively in contact. But the coaptation is rendered very exact, and a quick re-union much promoted, by drawing down the upper eye-lid, so as to shut the eye; in which state, the cartilaginous tarsus of the upper eye-lid makes an uniform compression on the cornea, in a manner which is extremely useful. Cuts of the sclerotica are not in general so simple. The choroides and retina may be at the same time either divided or exposed. In the first case, the expulsion of the whole of the vitreous humour, and a total disorganization of the eye, are to be apprehended from the immediate spasmodic contraction of the muscles of this organ; and, in the second, a violent and dangerous ophthalmia is to be expected. When, in the instance of a large wound of the sclerotica, choroides, and retina, the contents of the eye-ball are discharged, the organ inflames, and gradually shrinks into a much smaller mass, which is moveable, and capable of supporting an artificial eye.

Contused wounds of the eye-ball are mostly followed by a destruction of the functions of the organ, either in consequence of the concussion of the retina, or of the inflammation to which these injuries usually give rise. However, in a few cases, even contused wounds of the eye have united very favourably, and without the loss of vision. Sometimes the solution of continuity extends through the sclerotica, while the conjunctiva itself is not ruptured. Delpsch affirms, that he has seen several such cases, in which the latter membrane presented the appearance of an ecchymosis opposite the division of the sclerotica, and confined the humours of the eye, which otherwise would have been lost. *Précis des Maladies Chir.* tom. i. p. 349.

Nothing is more likely than gun-shot wounds to produce a violent concussion of the retina, and an incurable paralysis of this nervous expansion. The smallest particle of lead, which either strikes or penetrates the eye-ball, may occasion those effects. Every other severe contusion of the eye may act in the same way. When the extravasation of blood originating from an accident of this kind is not attended with a serious concussion of the retina, the effused blood will be absorbed, and the functions of the eye restored.

In all cases of wounds of the eye, says M. Delpsch, there are three fundamental indications; first, to prevent the expulsion of the vitreous humour and crystalline lens; secondly, to promote the quick re-union of the wound by placing its edges very accurately together; and thirdly, to do

WOUNDS.

do every thing in our power to avert inflammation. The two first objects cannot be fulfilled without keeping the eye-lids continually closed. The prompt re-union of the wound is one of the most effectual means of preventing inflammation; but when this affection cannot be entirely hindered, it is to be resisted by the kind of treatment which is explained in the article OPTHALMY.

Wounds made with pointed instruments may pass through the eye-lids into the orbit, and thence through the thin bones which compose this cavity into the brain; or the weapon may penetrate directly between the eye-ball and side of the orbit into the brain. Injuries of this description generally prove fatal on the spot, though sometimes the patient lingers for a few hours.

In many instances, an injury by a ball, inflicted in the neighbourhood of one eye, produces paralysis of the other. Pierre Roussillier, of the 25th regiment of the line, in the service of Napoleon, (says Mr. Hennen,) was wounded on the 18th of June, at Waterloo. The ball entered the right eye; the left, though not in the slightest degree injured to appearance, was completely blind. Rare, however, are the cases where death does not follow all wounds, particularly small punctured ones, going directly forward into the orbit, as this did. I felt under the zygoma, and all along the neighbourhood of this poor fellow's wound; but in the puffy state of the parts could not detect the course of the ball. He himself was confident it had gone into his brain. He returned to France convalescent. Garengot (*Traité des Operations*, vol. iii. obs. 20.) gives us an interesting case from the lectures of Petit, in which a soldier received a wound towards the great angle of the eye. It was deemed but of little consequence, and healed under the common hospital treatment. The man expressed a wish to leave the hospital, although cautioned by the surgeon, and had scarcely reached the door when he was seized with rigors, obliged to return, and died in two days. On dissection, the ball was found lodged under the sphenoid cells and the hole of the optic nerve. The effect on this man's sight is not mentioned." Hennen's *Obs. on Military Surgery*, p. 360.

Wounds of the lower part of the forehead, or eye-brow, are sometimes followed by the disorder named *ptosis*, in which the upper eye-lid hangs down more or less over the eye; but more commonly they give rise to an opposite complaint, called *lagophthalmus*, in which, from a contraction of the cicatrix, the skin is drawn up, and the upper eye-lid cannot be made to cover the eye. See those terms.

Wounds of the eye-brows sometimes cause a species of blindness named the *gutta serena*. This consequence is commonly thought to be owing to an injury of the nervous filament, which comes out of the orbit at the notch in the superciliary ridge. It is very probable, however, that the affection of the eye is not altogether dependent on the injury of the nerve; for the blindness very often occurs when the cut is not situated near the track of the nerve, and frequently does not occur when the nerve is known to be wounded. According to Richter, it is when the wound is nearly or quite healed that the event is most likely to happen.

Scarpa has set down the *gutta serena*, arising from an injury of the supra-orbital nerve, as absolutely incurable; but we know that this statement is not altogether correct; for Mr. Hey has recorded in the *Med. Obs. and Inquiries*, vol. v. an example of amaurosis which got well, though it originated from a wound of the eye-brow. See *GUTTA Serena*.

Mr. Hennen says, he has met with one or two cases of amaurosis from wounds of the supra-orbital nerve. The per-

fect division of the nerve did no good; but after some time the eye partially recovered. On *Military Surgery*, p. 366.

Wounds of the eye-lids scarcely admit of an effectual application of adhesive plaster, and their edges are generally brought together with a suture. There are some practitioners, however, and amongst them is M. Delpech, who consider the use of sutures, even in these cases, quite unnecessary. *Précis des Maladies Chir.* tom. i. p. 346.

Sabre-strokes, directed obliquely downward against the face, very often produce a wound with a flap, which should be immediately laid down in its proper situation again. When the flap is large and muscular, Richter thinks it best to use a suture at one or two points, as the strips of adhesive plaster are apt to become displaced, especially if the patient is restless, and then the flap of skin, not being sufficiently retained, slips downwards, and the part is not healed without deformity. However, it certainly has always appeared to us that a suture in this instance may be dispensed with, if care be taken to assist the effect of the adhesive plaster with a compress and bandage. *First Lines of the Practice of Surgery*, p. 291. edit. 3.

Sabre-wounds sometimes break and splinter the bones of the face. The fracture, however, seldom extends far, because most of these bones are soft and spongy. Notwithstanding such injury of the bones, the wound of the soft parts frequently admits of being united, if care be taken to extract all the splinters, and put the surfaces of the division of the bones as evenly together as possible. Unless the fragments are quite detached they should never be taken away, but be replaced as well as circumstances will permit. Their removal is not an easy matter, it occasions an unpleasant disfigurement, and experience proves that all divisions of the bones of the face heal with particular readiness. (*Anfanggr. der Wundarzneeykunst*, b. ii. p. 244. edit. 3.) A very terrible sabre-wound of the face is recorded by Mr. Hennen. The weapon struck an officer nearly across the eyes, one of which it destroyed; it then divided the parts downwards and inwards to such an extent, that the pharynx could be seen. Yet the injury healed in a very favourable manner, as indeed do all wounds of the face, owing to its great vascularity. See *Obs. on Military Surgery*, p. 370.

In some horrid cases, where the lower jaw is swept away by a cannon-shot, life is preserved; but, in general, the patient sinks under the accumulated tortures of his situation. "It is still, however, our duty," as Mr. Hennen observes, "to try every expedient; and after the ragged parts and splinters of bone are removed, the vessels within reach secured, and the suppurating process fairly established, we may endeavour to assist nature, faithfully following any effort she may make to fill up the chasm, but without allowing ourselves to count upon a showy or complete cure." (*Op. cit.* p. 373.) This gentleman saw a horrid-looking case, in which nearly one half of the face was carried away by a round shot at Waterloo, in a very fair progress of contraction. Larrey has likewise recorded a similar cure; and the writer of this article once witnessed in Holland a most extraordinary recovery of the same nature. It was the case of a soldier, wounded at the assault of Bergen-op-Zoom, in 1814, who was afterwards brought into one of the military hospitals of Oudenbosch. All the lower jaw, and a large part of the upper, were in this instance completely torn away. There was very little hemorrhage, and no vessels required the ligature.

For some observations on wounds of the tongue, we beg to refer to the article *TONGUE*.

When a part of the nose is divided, but not entirely detached, it is the duty of the surgeon to replace it as expeditiously as possible. When adhesive plaster does not appear to

be capable of securing the part in its proper situation, a future may be employed. Writers usually advise keeping the nostrils pervious with soft flexible tubes, chiefly with a view of giving vent to the mucus which is secreted by the inflamed Schneiderian membrane, and which, if it could not readily escape, might prove exceedingly annoying to the patient. Putting out of the question Garengot's extraordinary case, and a few others to which we have already adverted in a previous part of this article, we have many facts on record, proving not only that most incised wounds of the nose admit of union, but also that contused ones, attended with an almost complete detachment of the part, may often be united. In one instance, the cartilaginous portion of a young man's nose was nearly bit off by a horse, the separated piece only hanging by a thin portion of skin; yet after being replaced, and three stitches made, the part was united without any material deformity. Richter's Chir. Bibliothek, 6 band, Seite 538, and Cooper's First Lines of Surgery, p. 282. edit. 3.

As the parotid duct passes beneath the integuments of the cheek over the masseter muscle, it is much exposed to wounds, which, if not properly treated, end in what are termed salivary fistulæ. Having considered this subject in a separate article, (see *Salivary FISTULA*,) we shall not dwell upon it at present. A late writer informs us, that in injuries of the parotid duct he has sometimes derived advantage from making the division complete by a clean incision across the duct into the mouth, and closely bringing together the edges of the wound on the outside of the cheek. The natural flow of saliva into the mouth kept the wound from healing up on the inside of the cheek. Hennen's Military Surgery, p. 374.

With respect to wounds of the external ear, experience has fully proved that they are cases which usually terminate favourably. Incised wounds and fibre-cuts of the ear mostly heal extremely well. Ravaton has recorded a case in which the ear united again, although it had been nearly separated from the head; and another instance of such success is mentioned in Cooper's Dict. of Surgery, art. *Wounds*. These and many other facts which might be quoted leave no doubt of the propriety of always making an attempt to unite parts, whenever the least connection between them remains.

Surgical authors differ in their statements about the effects of the total loss of the external ear upon the power of hearing. Thus it is asserted by M. Richerand, that the external ear, which is a sort of instrument calculated for concentrating the rays of sound, may be totally cut off without deafness being the consequence. For a few days after the loss, he says, the hearing is rather hard; but the infirmity gradually diminishes, the increased sensibility of the auditory nerve compensates for the imperfection of the organic apparatus, and the acuteness of the sense is entirely restored. (Richerand, *Nosographie Chirurgicale*, tom. ii. p. 122. edit. 2.) However, if we are to credit the statement of other writers, the recovery is far less complete than M. Richerand represents it to be. Thus Leschevin notices, that they who have lost the external ear, or have it naturally too flat, or ill-shaped, have the hearing less subtle. The defect can only be remedied by an artificial ear, or an ear-trumpet, which receiving a large quantity of the sonorous rays, and directing them towards the meatus auditorius, thus does the office of the external part of the ear. *Prix de l'Acad. Royale de Chirurgie*, tom. ix. p. 120. edit. 12mo.

Wounds of the external ear, whatever may be their size and shape, do not require a different treatment from that of the generality of other wounds. The re-union of the divided part is the only indication, and it may be in most instances easily

fulfilled by means of methodical dressings. Such writers as have recommended futures for wounds of the ear, (says Leschevin,) have founded this advice upon the difficulty of applying to the part a bandage that will keep the edges of the wound exactly together. The cranium, however, affords a firm and equal surface, against which the external ear may be conveniently fixed. Certainly, it is not more easy to secure dressings on the nose than the ear; and yet cases are recorded in which the cartilaginous part of the nose was wounded, and almost entirely separated, and the union was effected without the aid of futures. See *Mem. de M. Pibrac sur l'Abus des Sutures*, in *Mem. de l'Acad. de Chir.* tom. iii.

In wounds of the ear, then, we may conclude that futures are generally useless and unnecessary. As examples may occur, however, in which the wound may be so irregular and considerable as not to admit of being accurately united, except by this means, it should not be absolutely rejected. An enlightened surgeon will not abandon altogether any curative plans; he only points out their proper utility, and keeps them within the right limits. When sticking-plaster, simple dressings, and a bandage, that makes moderate pressure, appear insufficient for keeping the edges of a wound of the ear in due contact, the judicious practitioner will not hesitate to employ futures.

When a bandage is applied to the external ear, it should only be put on with moderate tightness, since much pressure gives considerable uneasiness, and may induce sloughing of the part. In order to prevent these disagreeable effects, M. Leschevin advises us to fill the space behind the ear with soft wool or cotton, against which the part may be compressed without risk. *Op. cit.* p. 119.

In the application of futures, the ancients have cautioned us to avoid carefully the cartilage, and to sew separately, one after the other, the skin of both sides of the ear. They were fearful, that pricking the cartilage would make it mortify, "ce qui est souvent-fois arrivé," says Paré. But notwithstanding so respectable an authority, the moderns make no scruple about sewing cartilages. In wounds of the nose, Verduc expressly directs the skin and cartilage to be pierced at once in applying futures, and the success of the plan is put out of all doubt by a multitude of facts. The same treatment may also be safely extended to the ear. See Leschevin's *Obs.* in *Op. cit.*, and Cooper's *Dict. of Pract. Surgery*, art. *Ear*.

Wounds of the Throat.—As Mr. John Bell has observed, there are several anatomical points which should be well remembered by the surgeon in all cases of wounds about the throat. First, it is to be recollected, that the arch of the aorta lies in the upper part of the chest in front of the trachea; and that where the carotid arteries come out of the chest to go up along the neck, they are scarcely at the sides of the trachea; they rather run before it. But, that as the arteries mount up the neck, they incline more to the side of the trachea; and that at the upper part of the neck, they are entirely behind that tube; for they incline towards the angle of the lower jaw, and having reached it, they begin there to give off their branches both to the head and neck. Hence we see the reason why a wound at the lower part of the neck is very often fatal, while a wound higher up is generally less dangerous. The suicide seldom strikes at the lower part of the neck; and it is from the accidental circumstance of his cutting very high up, near the chin, that the carotids escape.

Secondly, as the same author has explained, it should be remembered, that the carotid artery, the great jugular vein, and the par vagum, or eighth pair of nerves, lie very closely

WOUNDS.

connected with each other, being all inclosed in one mass of cellular substance, which forms something like a sheath for them. Now, says Mr. John Bell, since this eighth pair is one of the greatest nerves of the viscera, and since, by experiments upon animals, we know well that a wound of it is more fatal than a wound of the brain itself, this puts an end at once to all questions about the way of managing wounds of the carotid artery, or of the great vein. No doubt these may sometimes be partially wounded and the nerve escape; but, in general, the nerve will be cut along with them; and, at all events, the fatal consequences which would arise from including this nerve in a ligature, make it absolutely necessary that whenever the carotid is tied, it be first carefully separated from every other part. See John Bell's Discourses on Wounds, p. 415. edit. 3.

That the internal jugular vein, or the carotid artery itself, may sometimes be partially injured, without a wound of the par vagum, or the patient instantly perishing, has now been fully proved. The writer of this article knew of a case, which happened in the campaign in Holland in 1814, where the internal jugular vein was ruptured by the passage of a musket-ball down the neck; and yet the patient lived more than an hour after the accident, and when he died it was from suffocation, in consequence of the pressure of a large mass of extravasated blood upon the trachea. M. Larrey has related a very singular case: an officer received a gun-shot wound, which cut the external carotid at its separation from the internal, and in its passage through the parotid gland. Pressure made by an intelligent soldier at the moment, and subsequent bandages, saved the patient. (See Mémoires de Chir. Militaire.) This case is singular, because it is very uncommon for hemorrhage from so large a vessel as the external carotid to be permanently stopped by simple pressure, nor should we recommend the method to be imitated; for there is not in all surgery a better rule than that of trusting only to the ligature in every wound of a great artery. Mr. Hennen, however, informs us, that he knew of an English officer, who was also saved in India from the effects of an arrow wound in the carotid by the same means. (Obs. on Military Surgery, p. 180.) Such a mode of treatment we believe would fail a thousand times in succession; and the alleged cures would be more valuable, if it were always quite impossible to mistake hemorrhage from a branch for a bleeding from the trunk itself.

The writer of this article is acquainted with an army surgeon, in whose veracity he perfectly confides, who states, that he was once called to a soldier who had wounded the trunk of the carotid with a bayonet. The vessel was instantly taken up, and the man's life saved. In a modern publication may also be found another example, in which the carotid burst, and was taken up on the spot by Mr. Fleming, a naval surgeon. See Medico-Chir. Journal, vol. iii. p. 2.

Without positively maintaining, as Mr. J. Bell does, that it is impossible to cut through the trachea so as to open the œsophagus, without wounding the carotid artery, the jugular vein, and the eighth pair of nerves, we join him in believing that such an accident must be exceedingly rare. How then are we to explain the many alleged cures which are said to have been effected, notwithstanding the windpipe and œsophagus are stated to have been both cut through? We are to account for these extraordinary narratives in the manner so well pointed out by Mr. John Bell. "The fact is (says he), that neither the œsophagus nor the trachea is touched in the least degree, but the wound is much above them; for a suicide always strikes immediately under the chin. This wound, as far as I have observed, commonly

falls in the line which divides the neck from the chin; that is, the place where the os hyoides lies, and he commonly cuts the os hyoides away from its connection with the thyroid cartilage, or pomum Adami. In that case, the thyroid cartilage, forming the uppermost part of the larynx, is not touched; the rima glottidis lies below the wound quite safe. The wound indeed separates the epiglottis from the glottis; but it leaves the glottis and the larynx quite safe. It only separates the larynx from the root of the tongue; it is properly a wound in the root of the tongue; it is rather a wound of the mouth than of the throat; and when the food comes out, along with spittle and froth, it is by rolling over the root of the tongue." On Wounds, p. 417.

That, however, the trachea and œsophagus may be both cut in a few cases, without immediate death from hemorrhage, we decidedly believe, because there are too many facts on record to admit of any doubt on the subject. See Default's Journal and Saviard, obs. 58. Hennen's Military Surgery, p. 386.

In these high wounds of the throat, it is the superior thyroid artery which is most frequently cut. This vessel, after quitting the external carotid at the angle of the jaw, passes along the side of the upper part of the trachea, inclining forward towards the thyroid gland in its descent, and being therefore much exposed to the edge of the razor. The bleeding from this artery is profuse, and if not speedily stopped is as fatal as hemorrhage from the carotid itself. In some of these cases, the bleeding also proceeds from branches of the lingual artery.

Wounds of the carotid artery, or jugular vein, commonly prove immediately fatal from loss of blood, before any assistance can be obtained. If a surgeon, however, were to arrive in time to render aid, it would be his duty immediately to apply a ligature both below and above the wound of the vessel. This is the only plan which affords any chance of saving the patient's life, and, as we have already noticed, it has actually been done with success in a few uncommon instances, in which the surgeon was not too late. In passing the ligatures beneath either of those vessels great caution is requisite; for the eighth pair of nerves lies close to it, included in the same sheath of cellular substance, and the inclusion of so important a nerve in the ligature would have fatal consequences. Its situation on the outside of the artery, between it and the jugular vein, should therefore be always carefully remembered. According to Richter, the internal jugular vein has actually been tied with success. Small wounds of the same vessel, if we are to credit the accounts of this author, may sometimes be healed by means of a graduated compress, which must be retained on the part with a bandage, or, if that prove irksome, with the finger. One thing, however, is essential; namely, the pressure must on no account be remitted, until the wound in the vessel is closed. Richter's Anfanggr. der Wundarzn. b. iv. p. 173., and Cooper's First Lines of Surgery, p. 386. edit. 3.

M. Pelletan once saw a wound of the throat, which proved fatal in consequence of hemorrhage from the external jugular veins; and the same eminent surgeon met with another curious instance, in which a boy, who was convalescent after a cut of his throat, suddenly fell down in a state of suffocation and died: on examining the parts after death, it was discovered, that the left side of the epiglottis had been detached from the glottis and root of the tongue, and that in this loose unconnected state it had fallen upon the rima glottidis, and closed it so completely as to cause instantaneous suffocation. See Leveillé's Nouvelle Doctrine Chir. tom. i. p. 342, 343.

WOUNDS.

Wounds of the trachea are either simple or complicated. In both descriptions of cases, the usual symptoms are, an emission of air between the lips of the wound, loss of the voice, and sometimes emphysema. Such injuries of the windpipe as are not complicated either with hemorrhage, emphysema, or loss of substance, may for the most part be easily cured by means analogous to those which are employed for the cure of wounds in general. The re-union is still more easily accomplished, when the trachea is divided longitudinally, than when it is cut transversely. If the wound be of a certain size, and attended with hemorrhage, the first indication is to tie the bleeding vessels, and, in particular, to obviate the inconvenience and danger which would result from the insinuation of the effused blood into the windpipe; an occurrence which has sometimes proved fatal. (Wilmer's Cases and Remarks in Surgery, p. 92.) In order to prevent such an unfavourable event, some surgical writers recommend the external wound not to be closed while any oozing of blood continues, so that this fluid may readily find an external outlet, instead of falling into the trachea. (Lassus, Pathologie Chir. tom. ii. p. 291.) To us it appears, that the best mode of preventing the occurrence is to bring the edges of the wound of the trachea into contact by a suitable position of the patient's head, and, if requisite, even by a suture.

The greater sensibility of the larynx, its complicated structure, and the number and size of its blood-vessels, *ceteris paribus*, render wounds of it much more dangerous than those of the trachea. In the first volume of the Mémoires de l'Acad. de Chirurgie in 4to. many cases may be consulted which furnish proofs of this observation. In general, however, wounds of the thyroid cartilage heal very favourably, when not accompanied with injury of other important parts.

Transverse wounds, dividing only the anterior half of the upper part of the trachea, usually have a favourable termination, and when the cases are of this description, the carotids and jugular veins for the most part escape injury. Gun-shot wounds of the trachea are more dangerous, but experience proves that they also frequently end well.

The greater number of transverse wounds of the trachea, which have not divided this tube completely through, readily admit of cure by the strict observance of a proper position. When the patient's chin is brought downward and forward towards the sternum, and the head is maintained in this posture with pillows, the edges of the wound in the trachea become spontaneously approximated to each other, and in time will grow together.

The manner in which the employment of sutures aggravates the cough, and inflames the wound, often necessitates the surgeon to withdraw them when they have been applied. It may also be truly asserted, that besides the irritation which they create in the trachea as extraneous substances, they are (to say the best of them) very unnecessary. Nothing has a greater tendency to impede the union of a wound of the trachea than the disturbance of a frequent convulsive cough; and the irritation of sutures always increases this hurtful symptom in a much greater degree than they can do good by maintaining the edges of the wound in contact. In fact, unless the greater portion of the diameter of the trachea be divided, there never can be such a space between the edges of the wound, that they cannot be brought together with the assistance of a judicious posture of the head.

When the patient is much afflicted with incessant coughing, and the inflamed state of the wounded parts appears to operate as the cause of this disagreeable symptom, relief is

to be obtained from bleeding, and the exhibition of soothing and aperient medicines. In cases in which no particular local irritation can be suspected of giving rise to the cough, the surgeon may prescribe the almond emulsion, Spermaceti mixture, and opium, which will frequently be found remedies of the most decided efficacy.

In order to prevent the entrance of the discharge and blood into the trachea in particular instances, the plan has been tried of making the patient lie on his side, with his face turned downwards. (See Mém. de l'Acad. de Chir. tom. i. p. 581.) But, although the case here referred to ended well, we believe, as already explained, that nothing prevents the entrance of blood or matter into the trachea so effectually as keeping the edges of the wound of this tube accurately in contact, which is to be principally effected by bringing the chin down towards the breast. This is an object which is far more difficult of accomplishment, where the patient lies on his side, than when he remains, as is most usual, upon his back.

When a wound has detached the upper portion of the trachea from the lower one, and it is not immediately fatal from the injury of other important parts, the bleeding vessels are first to be tied, and the two ends of the trachea are then to be brought into contact. In this sort of case, we believe that the employment of a suture is warrantable, on account of the immense separation of the divided parts, and the inefficacy of position alone to prevent it. But, even in such a case, one suture will be quite enough when the chin is properly approximated to the sternum, and the needle should never be introduced through the membranous lining of the windpipe, as it is very sensible, and much disposed to inflammation.

The hoarseness and weakness of the voice, sometimes remaining after the wound is healed, often gradually disappear.

Many surgical writers recommend the patient to refrain from making forcible expirations, and from drawing the head suddenly backwards, for a certain time after the wound is healed. By such causes, it is asserted, the recent coalescence of the wound may be easily destroyed.

Wounds made with bullets, which strike the side of the neck and lacerate the trachea, have frequently been observed to terminate well. (Mém. de l'Acad. de Chir. tom. iii. p. 151, &c. edit. 12mo.) Ravaton mentions several instances, which not only got well, but were also followed by a recovery of the voice.

Sutures are not applicable to these cases. A strict adoption of the position recommended above, and the application of an emollient poultice contained in a fine linen bag, are the chief local surgical measures. The use of leeches, venesection, saline medicines, and antiphlogistic remedies of every description, will also be generally proper. (See First Lines of Surgery, p. 387. edit. 3.) Opium is likewise not to be forgotten as an extremely useful medicine in cases of wounds about the throat: it not only appeases the cough with which such injuries are often accompanied, but tends to quiet the great mental and nervous anxiety which in examples of attempted suicide existed previous to the infliction of the wound, and generally continues for some time afterwards in a very aggravated degree. Indeed, many of the unhappy persons who attempt to destroy themselves by cutting their throats, still retain for a good while after the failure of the first attempt, a determination to take another opportunity of accomplishing their fatal purpose; hence such patients cannot be too closely watched, and nothing like a razor or a knife should ever be put within their reach. The necessity of a constant vigilant attendant is also

also necessary, in order to hinder the dressings from being pulled off, and the wound torn open again, by the restless movements or actual violence of the patient.

In cases in which the whole diameter of the trachea is cut through, the French surgeons have proposed the introduction of a flexible catheter from one of the nostrils into the larynx and trachea, in order to insure a passage for respiration, which, they say, without this means is liable to be completely intercepted when the outer wound is closed, in consequence of the two portions of the windpipe being drawn away from each and not corresponding. (Richter, *Nosogr. Chir. t. iv. p. 170. edit. 4.*) This, however, would not be the practice to which we should give a preference; first, because the introduction of a flexible catheter is a thing which cannot always be accomplished with facility; secondly, because its use in this way is constantly productive of considerable irritation; and, thirdly, because we deem the employment of a future the best means of hindering one part of the trachea from becoming separated far from the other, and thus of insuring a passage for respiration.

With respect, however, to the introduction of a flexible catheter from one of the nostrils into the œsophagus, for the purpose of giving food and medicines to the patient, without any motion or disturbance of the wounded parts, we consider the method entitled to the highest praise in all cases of serious wounds, either of the larynx, the trachea, or the œsophagus. When a person swallows, the muscles concerned in the elevation and depression of the larynx act in a sudden convulsive kind of manner, and cause a most injurious disturbance of the wound. But when nourishment and medicines are injected into the stomach through a flexible tube, introduced from one of the nostrils down the œsophagus, this hurtful action of the muscles is entirely prevented; the instrument may be kept there without any annoyance or irritation, and the requisite quantity of aliment, and whatever internal remedies may be indicated, can be given with the utmost convenience. We consider this use of flexible catheters as constituting a very material improvement in the treatment of severe wounds of the throat. The military surgeon, in particular, should never be without these instruments; and whoever has read the relations of M. Larrey, in his *Mémoires de Chirurgie Militaire*, will see, that sometimes in bad wounds of the throat, the patient's chance of recovery depends almost entirely upon the aid to be derived from the skilful employment of an elastic gum tube.

Wounds of the œsophagus may either amount to a total or partial division of that tube; they may be either with or without a total division of the trachea; and with or without injury of other important parts in the vicinity. Hence such wounds are sometimes absolutely fatal; and, in general, when they admit of cure, nature has a greater share than art in bringing it about. Some benefit, however, is to be derived from good surgery, and infinite harm may result from bad.

A total division of the œsophagus must prove immediately fatal. The inevitable simultaneous injury of other important parts would render such a case at once mortal. The celebrated Prussian surgeon, Schmucker, has treated small wounds of the pharynx and upper part of the œsophagus with success. Wounds dividing half or even two-thirds of the tube are also stated to have been cured. (*Mém. de l'Acad. de Chir. tom. iii. p. 151. edit. 12mo.*) The possibility or impossibility of a cure must obviously depend upon what other parts of consequence are injured.

Incised wounds, which divide the front of the œsophagus, must derive additional danger from the simultaneous division

of the whole circle of the trachea; and, indeed, so much would the internal jugular vein, par vagum, and carotid artery, be exposed to the edge of the knife in a cut of this kind, that it is difficult to conceive how they can ever escape. Mr. John Bell, as we have seen, believed that they never could; and were it not for the many examples published, some of them by such a man as Default, and for an instance which was lately in St. Bartholomew's hospital, we should have joined Mr. J. Bell in thinking, that all reports of this kind were mistakes, arising from the wound extending through the root of the tongue into the mouth, and not actually injuries of the œsophagus itself.

A punctured wound, penetrating the side of the œsophagus, may not be complicated with injury of the trachea, and therefore may not be attended with so much peril as an incision. But although stabs injuring the œsophagus are not regularly and certainly mortal, they are always to be regarded as dangerous cases.

Should the case be one of those fortunate incised wounds which leave the great vessels uncut, though the injury of the œsophagus be complicated with a complete division of the trachea, the surgeon can lessen the space between the edges of the wound in the œsophagus by bringing the divided portions of the trachea together. This effect must result from the manner in which the posterior part of the windpipe is connected with the œsophagus. But for this purpose, a future is only to be used in such a state of the wounded trachea as amounts to a total division of the tube; for in all other cases, a proper position of the head, and the use of adhesive plaster to the external wound, should be the means with which the surgeon ought to be content, with a view of bringing the margins of the wound of the trachea near to each other.

In cases of wounds of the œsophagus, it was recommended, as long since as the time of Ravaton, to inject nourishment and medicines into the stomach, through a smooth tube of a suitable size, introduced down the pharynx. In one case of paralysis of the œsophagus, which occurred in this country, a small fresh eel-skin was passed down this canal, by means of a whale-bone probang, in order that medicines and food might be injected into the stomach. (Hunter, in *Trans. for the Improvement of Med. and Chirurgical Knowledge.*) The many cases, however, in which Default advantageously employed an elastic gum catheter for the same objects had a principal influence in establishing the practice. The instrument was introduced through one of the nostrils, and was often left in the œsophagus for several days together. (See *Œuvres Chir. de Default par Bichat, tom. ii.*) The introduction of elastic gum catheters down the pharynx and œsophagus is not only highly necessary in examples of paralysis, and wounds of those passages, but it is an exceedingly useful practice in wounds of the trachea, where the convulsive action of the muscles in deglutition would otherwise create a very hurtful disturbance of the injured parts. (*First Lines of Surgery, p. 38, 39. edit. 3.*) The practice is also sometimes absolutely necessary in many complicated wounds about the face, such as those produced by the discharge of a pistol into the mouth, and attended with extensive laceration of the tongue, cheeks, and fauces, and a comminuted fracture of the lower and upper jaw-bones. We believe, indeed, that in all fractures of the lower jaw, the introduction of a flexible catheter from one of the nostrils into the œsophagus is an extremely judicious measure, because the action of deglutition has a greater effect in displacing the broken bone and disturbing the process of union than any other circumstance.

Gun-shot wounds of the neck sometimes occasion an immediate loss of the use of the arm on the affected side; a circumstance which may in general be accounted for by the injury of some of the cervical nerves, in their descent to and from the axillary plexus. See Hennen's Military Surgery, p. 378, and Thomson's Report of Observations made in the Military Hospitals in Belgium, p. 75, 76.

Wounds of the Thorax, or Chest.—Some of these injuries penetrate the cavity of the thorax; others are more superficial, only affecting the skin and muscles, and not extending through the pleura costalis. When the latter cases are produced by sharp-cutting instruments, and the only indication is to accomplish an union of the divided parts, as happens in incised wounds of the skin, latissimus dorsi, pectoralis major, &c. such injuries are not materially different from any simple wounds of other parts of the body, and require a similar mode of treatment.

But where much violence has been applied to the parietes of the chest, and the concussion has operated so forcibly as to affect the heart, lungs, and other important organs, the wound, although simple in appearance and not penetrating the chest, may nevertheless be followed by alarming symptoms, either at first or consecutively; such as inflammation of the lungs, spitting of blood, and difficulty of breathing, as is frequently observed in contused and gun-shot wounds of the parietes of the chest. A violent blow on the dorsal vertebræ is also said to have given rise to a dilatation of the heart, and an aneurism of the aorta. Laffus, Pathologie Chir. tom. ii. p. 305.

Thus professor Thomson, in his account of the wounded whom he observed after the battle of Waterloo, remarks, "We saw more instances than one in which a ball, in passing across a portion of the parietes of the thorax, without penetrating that cavity, had excited an alarming and dangerous degree of inflammation of the pleura. In one of these, the ball had taken an oblique direction along the lower part of one of the sides of the chest. In another it had struck against a strong leathern belt that was suspended over the right shoulder, made a deep indentation in this belt without penetrating it, and produced a severely contused wound at the inner extremities of the first and second ribs of the right side. This patient suffered much from inflammation. The injured portions of the ribs had exfoliated and come out, and the motion of the lungs in inspiration and expiration was perceptible from the sinking and rising of that part of the parietes which had been deprived of its bony support. In another remarkable case, the ball entered above the middle of the clavicle, and passed out at a point directly behind. Neither at the first, nor at the time we saw this case, was there any reason to believe that the ball had wounded the pleura. Inflammation, however, of this membrane came on, which terminated in suppuration. The operation for empyema was performed, and about four pints of pus evacuated." Reports of Obs. in the Mil. Hospitals in Belgium, p. 82.

In wounds of the chest, it is often difficult to pronounce with certainty whether they penetrate into the sac of the pleura; but all doubts with regard to this point are removed the moment we observe air coming out of the wound upon coughing. That the lungs have been wounded may be inferred with nearly equal correctness in every case, in which a person spits blood immediately or soon after receiving a wound of the chest.

It rarely happens that a wound penetrates the cavity of the thorax without producing more or less injury of the lungs, and the danger of the latter accident is in proportion to its depth, its situation, and the size of the weapon with

which it was inflicted. A wound of the lungs with a small sword seldom gives rise to much effusion of blood in the chest, unless some of the large vessels of those organs happen to be hurt. Putting this circumstance out of present consideration, the usual symptoms which the patient suffers are, a spitting of blood, cough, and difficulty of breathing, succeeded by a good deal of symptomatic fever.

"To discover whether the wound has injured the lungs or not, (says a late writer,) is a point which has given to the older surgeons great room for employment of their ingenuity in devising possible cases, and has occasioned no small waste of time and wax-tapers in ascertaining the exit of air through the passage. A practical surgeon will require but little investigation; bloody expectoration immediately on receiving the wound, and the terrible symptoms of dyspnoea, sense of stricture and suffocation, insupportable anxiety and faintness which succeed, soon enough discover the fact; and if by good fortune no intimation is given in this way, happy is the surgeon, and thrice fortunate the patient.

"The immediate danger in wounds of the lungs is either from debility from hemorrhage, or suffocation from the blood flowing into the air-cells and cavity of the thorax. The effusion of air forming emphysema is also a troublesome, but (as Mr. Hennen believes), taking it abstractedly, is not a dangerous symptom of those injuries; neither (says he) is it by any means so frequent as has been supposed. The symptoms that I have now enumerated, whether single or in combination, may be deemed the primary effects of wounds of the thorax. Violent inflammatory affections of the lungs and the membranes ever subject to relapse; long and tedious suppurations and exfoliations of the bones are the secondary, and though not so rapidly fatal are often as certainly so as the others. Diseases which, although we cannot strictly call them pulmonary consumption, agree with it in many points, particularly in cough, emaciation, debility, and hectic, are often the consequences." Obs. on Military Surgery, p. 395.

When the weapon is broad, and it has entered the substance of the lung, the hemorrhage is considerable; blood is immediately extravasated in the cavity of the thorax, and also flows out of the external wound; the patient has a violent paroxysm of coughing, in which some of the blood is ejected from the mouth; the air comes out of the chest with a hissing noise; and if the outer wound be not parallel to that of the lungs, emphysema takes place. As we have already stated, the danger of such an injury depends upon the depth of the wound, and the size of the vessels which are opened. Some patients recover, while others die instantly, or in a very short space of time.

As an interesting author remarks, it is a thing really wonderful, "that the thorax, containing the heart, lungs, and great vessels, should be so often wounded with so little danger. Many no doubt die, but numbers escape; for a wound of the substance of the lungs is far from being mortal. The blood may suffocate the patient; the fever and pain may waste him; he may die of the inflammation, or of the oppression of the lungs; or there may be time for a large suppuration, or a lingering hectic to cut him off; but still, if his wound be only in the edges of the lungs, he is in some degree safe. He is only in danger when the thick substance of the lungs is perforated, and falls into abscess, or when the root of the lungs is wounded; for there the large vessels of the lungs being opened, the great effusion of blood, like that from a wound of the heart itself, must kill, even by the quantity of blood lost to the general system. But besides, this blood, being thrown into the trachea,

WOUNDS.

trachea, deluges the lungs; the patient spits up a frothy blood; blood, instead of air, occupies the bronchiæ; so that he struggles for breath but a few moments, and then expires." John Bell's Discourse on the Nature and Cure of Wounds, p. 257. edit. 3.

We shall next consider the treatment of penetrating wounds of the chest. In these cases, the patient may die instantaneously of internal hemorrhage and suffocation; or he may be cut off by the effects of inflammation within the cavity of the thorax. If (says Mr. John Bell) the patient be spitting blood and breathing high, but not much oppressed, or his oppression increasing very slowly, there are hopes that he may be saved. If there be no great vessel wounded in the lungs so as to suffocate him at once, it is probable that the smaller vessels which are opened by the wound will gradually cease to bleed; and after four or five days of alarming cough, with bloody expectoration, that symptom will cease; and in order that he may the sooner be relieved from his danger, *he must be bled very freely*. Let it be the intention to reduce him very low by quick bleedings; and let these bleedings (says Mr. John Bell) have the effect of continued internal hemorrhage, without the dangers of it. Let them depress him to the same low condition to which the inward bleeding would most likely have brought him; and the system being emptied in this direction, there will be less danger of immediate suffocation in the lungs, and but little fear of the succeeding inflammation rising too high. It is only by these repeated bleedings that the patient can be saved: the vascular system must be kept low in action, and so drained as to prevent the lungs from being oppressed with blood.

One thing (continues the same author) is very clear, that if the surgeon bleed only when the cough and bleeding from the lungs return, he never can do wrong. The patient, lying struggling before him, is to lose a given quantity of blood; if it be allowed to flow out into the lungs he may be suffocated; if it be drawn from the arm, this suffocation is prevented. If he be kept low enough by bleeding, there will be no blood to spare for this extravasation into the lungs, &c. (Op. cit. p. 259, 260.) We repeat, in all cases of penetrating wounds of the chest, and especially in injuries of the lungs, the free use of the lancet is the only thing which can be depended upon in the early part of the treatment. By it, internal hemorrhage is restrained; and by it, the dangers of the subsequent inflammation of the thoracic viscera are to be averted. The records of surgery furnish abundant proof of the necessity of such practice, and the extent to which the bleeding must be carried is sometimes surprising. Thus, in a case in which a musket-ball had entered the left shoulder, passed through the lungs, and come out below the left nipple, a profuse hemorrhage of arterial blood took place from the mouth, and threatened immediate suffocation. This hemorrhage was checked by repeated bleedings, which were resorted to on every fresh attack of the hemorrhage, and pushed till relief was obtained. Leeches were applied to the side in great numbers, and the antiphlogistic plan of treatment was strictly pursued. Two hundred and fifty ounces of blood were in this case drawn off by the lancet in eighteen days. (See Thomson's Reports of Obs. made in the Military Hospitals in Belgium, p. 86.) In every instance of a penetrating wound of the chest, and more particularly when the lungs are injured, the first bleeding should be copious. As Mr. Hennen recommends, from thirty to forty ounces of blood should be taken from the arm by a large orifice. If the patient should faint, we ought not to administer cordials to him, but allow him to revive gradually. We should avail

ourselves of this opportunity of extracting without pain all foreign bodies within reach, whether cloth, ball, iron, wood, splinters of bone, &c. Should there be reason to think that such extraneous substances are lodged, and that by an enlargement of the orifice of the wound they might be extracted, the practice ought to be immediately adopted.

The next object is to dress the wound itself. "If it is a gun-shot (says Mr. Hennen), a light mild dressing will be sufficient; but if incised, the lips of it should be closed at once, and this treatment will be found to afford the most certain preventive to emphysema (see EMPHYSEMA), future hemorrhage, and collections of matter. (See EMPYEMA.) I scarcely recollect an instance where it was necessary to remove the adhesive straps, or (where it was a gun-shot) the usual dressings. We now lay the man down, and let him remain as quiet as possible, and in as cool and airy a spot of the barn, church, or hospital, as we can find. He will often require no farther aid; but if the case is very severe, he will probably lie for some hours in a state of comparative ease, till the vessels again pour forth their contents, and induce fresh spitting of bloody froth, and a repetition of all the symptoms of approaching suffocation. The lancet must again be had recourse to; and if by this management, repeated as often as circumstances demand, the patient survives the first twelve hours, hopes may begin to be entertained of his recovering from the immediate effects of hemorrhage. In the after-treatment of a wound of the nature here described, we shall be considerably assisted by the aid of medicine; but until the danger of immediate death from hemorrhage is over, we must not think of employing any thing except depletion by the lancet: it, and it only, can save the life of the wounded man." Hennen's Obs. on Military Surgery, p. 398.

When the paroxysms of pain, the sense of suffocation, and return of hemorrhage, says Mr. Hennen, have become more moderate, and recur at longer intervals, we may have recourse to means of less immediate influence, and spare the lancet. In this view, the most powerful medicine that we can administer is the different preparations of digitalis, in such form as may best agree with the patient; and if the pain and efforts to cough are severe and spasmodic, we must have recourse to the aid of opiates. To this course of medicine should be added a rigour of diet, amounting to the total prohibition of every thing solid, and admitting of fluids only of the mildest nature and least irritating quality; and even those in small quantities, and duly acidulated. Should we be fortunate enough to preserve our patient during the first six or seven days, a relaxation in this rigour may be cautiously admitted; but a departure from the general plan, or an omission of bleeding on the rising of the symptoms, can only tend to accelerate the event that our efforts are designed to counteract. Mild saline purges, and an emollient enema, should be occasionally administered if required, and the patient kept in a state of the utmost quiet and seclusion from all external impressions, and in a cool atmosphere. (Op. cit. p. 400.) The plan of exciting a counter-irritation on the surface of the chest, by means of blisters, should also never be omitted, when much cough and pain in the breast continue after bleeding has been fully practised. In some examples, the inflammation occasioned by penetrating wounds of the chest terminates in suppuration within the lungs, or the sac of the pleura. The symptoms, however, which indicate such an occurrence, and the mode of treatment, are so amply explained in another part of this work (see EMPYEMA), that we shall not enter into the subject again.

There is one circumstance which sometimes deceives the surgeon,

surgeon, and leads him to suppose that the case is a penetrating wound of the thorax when it is not so. We allude to the occasional examples in which a musket-ball pierces the skin and muscles on the outside of the chest, runs round the ribs, and makes its exit nearly opposite the point of entrance. Here the absence of bloody expectoration and other symptoms of injured lungs, together with the direction of the commencement of the track of the ball, will sometimes convey useful information to the discerning practitioner.

There is also another source of deception as to the actual penetration of balls into the cavities of the body: this is when they strike against a handkerchief, linen, cloth, &c. and are drawn out of the wound unperceived in a fold or pouch of those materials. M. Larrey, Mr. Hennen, &c. have published examples of the occurrence.

Wounds of the chest are sometimes complicated with the lodgment of extraneous substances in that cavity, and this sometimes without occasioning fatal consequences, either immediately or subsequently. Thus Mr. Hennen informs us, that in examining the bodies of soldiers who have died from those injuries, he has frequently found pieces of wadding, of clothes, spiculae of bone, and balls, and, in one case, some charpie used as a dressing, either loose in various parts of the lungs, or lying in sacs, formed by a deposition of coagulating lymph. In some more fortunate patients who recovered, such matters were discharged or extracted from the wounds; and in certain other lucky examples they were ejected by the convulsive efforts to cough, which their irritation had excited. (Obs. on Military Surgery, p. 390.) The same author relates the following interesting case, to prove that a much larger mass than a bullet may pass even through the lungs, without doing away all chance of recovery.

A soldier of the guards was wounded through the thorax at Waterloo, between the third and fourth ribs of the right side. On his arrival at Brussels, he was placed in an hospital and dressed. Nothing remarkable occurred for the first five days; and the only singularity in the appearance of the wound was its large size, capable of admitting three fingers conically placed. Blood and air were freely discharged from it. On turning the man to examine him, and renew the dressings, a tumour was discovered on the scapula, from which was extracted his breast-plate, about two-thirds of which were rolled up by the force of the blow into a figure somewhat resembling a candle-extinguisher, with the musket-bullet contained within it. The other third was broken off; but it had also passed through the wound, and was extracted. The man survived the injury three weeks, and afforded great hopes of his perfect recovery; but in a gust of passion, he one night tore the dressings off his wound, and was found dead the next morning. The body was not examined. Op. cit. p. 392.

Balls have been found in the substance of the lungs twenty years after their entrance, the patient being all that time in perfect health, without any symptom characterizing the peculiar situation of such foreign bodies. There are also on record instances in which a ball has rolled about in the cavity of the thorax on every motion of the body. (See Baron Percy's *Manuel du Chirurgien d'Armée*, p. 25; Magatus's *Bibliotheca Chirurgica*; and Hennen's *Military Surgery*.) In general, however, balls lodged in the thorax become as it were encysted and fixed by the deposition of coagulable lymph around them, and the formation of a sort of sac.

Several authors have noticed, that when a penetrating wound of the chest is of a certain size, a portion of the lungs

sometimes forms a protrusion between the ribs. In the majority of such cases, there can be no doubt of the propriety of immediately reducing this sort of hernia, and keeping it so replaced by means of a suitable apparatus. We learn, however, from the observations which have been collected on this subject, that the protruded part of the lung has sometimes been tied, or cut away, without any ill consequences. Fabricius Hildanus records the case of a man who was wounded with a sword between the fifth and sixth ribs, near the sternum, and in whom a piece of lung protruded. On examination it presented a livid appearance, and the discoloured part was therefore cut away with a heated knife. The rest was reduced, after separating the two ribs, from each other, as far as possible, by a wooden wedge. Notwithstanding this extraordinary method of treatment, the patient soon recovered, and lived without experiencing any oppression in respiration. See *Centur. 2. Obs. 32. p. 108.*

The livid appearance of the lung, as M. Lassus observes, arises from its exposure to the air, and the manner in which it is strangulated between the two ribs. It affords no proof either that the protruded part is gangrenous, or that it ought to be cut away. (*Pathol. Chir. tom. ii. p. 309.*) A writer (says he) who is very little known, and whose case we shall relate, confesses his having mistaken this livid discolouration for a sign of mortification. A man received a stab between the third and fourth ribs, on the right side of the chest, and by the way in which the sword had been withdrawn, the wound was rendered very large. A portion of the lungs protruded, swelled considerably, and remained in this state three or four days without any attempt being made to reduce it. The part then became shrunk and quite dry, when the whole of what was exterior to the ribs was cut off. On dipping the piece of lung in water, however, it immediately resumed its natural colour, which, no doubt, it would also have done had it been reduced instead of being amputated. The patient nevertheless got quite well, and suffered afterwards no difficulty, notwithstanding the hard laborious life which he was obliged to lead. *Obs. Medicinales et Chirurgicales par Loyer, p. 25.*

A similar mistake was made on a patient who had received a wound which penetrated the anterior and inferior part of the chest. A small bit of the lungs protruded, which was supposed to be a piece of omentum, and was immediately included in a ligature. Ruych being consulted, perceived the mistake, and he recommended dressing the wound, and leaving things as they were, until the tied portion of lung had become detached. No bad symptoms followed, and the patient perfectly recovered. (*Obs. Anat. Chir. obs. 53.*) We met with a protrusion of a long piece of the lungs in a soldier, who had been wounded with a lance at the battle of Waterloo. The part was at least four inches in length, and shaped like a tongue. As it was considerably contused and torn, we doubted the prudence of returning it in that state into the chest. We thought, therefore, of cutting it off, but fearful that it might bleed freely, we first made a small incision into it, in order to ascertain the fact; and as a good deal of blood began to flow from this little incision, we first tied the protruded part close to the ribs, and then removed all that was exterior to the ligature. The patient was so well on the day of the operation, and also the next morning, that he would not remain in bed; but we were informed that he did not ultimately recover.

A wound of one of the intercostal arteries immediately produces a degree of hemorrhage, which is manifest externally, and often considerable. The blood flows out of the wound, and also into the cavity of the chest. It issues

per saltum, like that of all wounded arteries, and it gushes out both in inspiration and expiration, but without any hissing noise, and not blended with mucus and air, like the blood which is discharged from a deep wound of the lungs.

We should not have expected much hemorrhage from the intercostal artery when wounded by a ball, much less should we have expected that it was ever possible to take up that vessel with a tenaculum. Yet a late writer observes, "whenever the tenaculum can be used to an intercostal artery injured by a ball, it should at once be applied, and the vessel secured by ligature." (See Hennen's *Obs. on Military Surgery*, p. 401.) Professor Thomson heard only of one hemorrhage from the intercostal artery after a gun-shot wound received at Waterloo, and this was a secondary bleeding on the fifteenth day. It was stopped by a compress. See *Obs. on the Military Hospitals*, &c. p. 83.

This sort of bleeding can only be stopped by compression, and in order that the plan may be effectually practised, it is sometimes necessary to enlarge the wound by an incision. When the finger is put under the wounded artery the bleeding ceases, which obviously proves that there is no occasion for needles, nor for any particular inventions for stopping the hemorrhage. According to M. Lassus, it will be quite enough to introduce between the ribs a tent, or dossil of charpie, which is to be kept in the wound four or five days. The bleeding having stopped, the wound will discharge for some days a reddish purulent fluid, and if the lung be not perceptibly injured, the cure will be speedily effected by ordinary treatment.

The method which has been tried for stopping hemorrhage from a wound of the internal mammary artery is analogous to the foregoing. A man was stabbed with a sword, which entered obliquely between the cartilages of the ribs. The wound was not extensive; but the effusion of blood in the cellular membrane of the lateral and anterior part of the thorax was considerable. An incision was made in the integuments covering the mass of blood, and several coagula were removed. The hemorrhage was then stopped by introducing some agaric, which was fastened to a spatula, and by means of this instrument, pressed from within outward, under the cartilage of the rib, near the side of the sternum. The wounded artery was thus very exactly compressed, and the plan was continued several days and nights successively under the direction of a surgeon. Lassus, *Pathol. Chir.* tom. ii. p. 312.

An extravasation of a considerable quantity of blood in one of the cavities of the pleura is followed by such a train of alarming and urgent symptoms, that the patient dies of suffocation unless the fluid be discharged. This may be accomplished either by making the patient lie on his wounded side, if the wound can thus be made depending, and it be sufficiently ample, or enlarging it with a bistoury, when it is too narrow, or by making another opening in the thorax when the wound is situated too high up. (See *EMPHYEMA*.) If the hemorrhage still continue, and be considerable, after the first extravasated blood has been discharged, the patient generally perishes; but when the bleeding ceases, and the lungs are not extensively injured, he may recover. Nothing but the urgency of the symptoms of suffocation, arising from a dangerous degree of pressure upon the lungs and diaphragm, can justify a hasty determination to make an opening for the evacuation of the extravasated blood, or the equally pernicious plan of leaving the original wound open for the same purpose. If the surgeon require arguments in support of this remark, they are to be derived from the equivocal, uncertain, and irregular character of the

symptoms of an extravasation of blood in the thorax, and from the effect which even the discharge of such blood may have in renewing the hemorrhage, and making room for another effusion, in cases where the injured vessels are large. The blood, however, must be discharged when the symptoms of suffocation are urgent, and evidently owing to the pressure of the extravasation on the organs of respiration. The practice of making an opening will always be unsuccessful, when the wound of the lungs, besides being deep enough to give rise to an extravasation, is also complicated with emphysema of those organs, and the effusion of a considerable quantity of blood into their cellular and parenchymatous texture. In short, in a wound of this serious description, it does not constantly happen, that the only curative indication is to discharge the extravasated blood. The degree of danger depends upon the nature of the wound of the lungs, which is invisible, and of which it is sometimes difficult to form a correct judgment. Frequently an extravasation of blood in the pericardium, without injury of the heart, but a case which is always fatal, has been mistaken for an extravasation in the cavity of the left pleura. Sometimes, also, we may be deceived, and believe in the existence of an extravasation, while the symptoms of suffocation under which the patient labours may be owing to the substance of the lungs being changed as it were into a solid mass, by the effusion of blood and coagulating lymph in their texture, and the consequent compression of the air-cells.

Although it must be acknowledged, that the diagnosis of an extravasation of blood in the chest is not free from difficulties, the following are usually regarded as the symptoms which characterize the case, either in the primary or secondary form. In the first place it is obvious, that there must generally be a wound of the lungs, which is indicated by the issue of frothy blood from the wound, by the passage of air through the wound into and out of the chest, and by the patient spitting blood, or coughing it up in large quantities. If, however, the blood come from the intercostal artery, no blood will be coughed up. At the moment of receiving the wound, the patient falls into a state of syncope, and though the bleeding may not be very considerable, he is affected with cold sweats, and his pulse is feeble and small. In the course of a few days, notwithstanding a low diet, repeated bleedings, and perfect quietude, respiration becomes short, difficult, and laborious, and inspiration is observed to be performed more easily than expiration. The patient usually lies upon the side in which the extravasation is; and this side seems rather larger and broader at its lower part than the opposite side, on which the patient cannot lie without an aggravation of all his sufferings. When he tries to sit up in bed, he cannot remain in this position, unless he bends his body very much forwards, in order to facilitate respiration. About the xiphoid cartilage and the lateral parts of the chest, he feels a weight, attended with a frequent cough, and a sensation of suffocation. According to Valentin, a large ecchymosis, or violet-coloured spot, makes its appearance in some individuals in a later stage of the case about the angles of the false ribs; but this symptom is far from being constant, and it did not occur in an instance of extravasation of blood in the thorax recorded by Dr. Thomson. (Reports of Observations made in the Military Hospitals in Belgium, p. 85.) In general, blood escapes from the wound, unless the opening be very small, or situated in the upper part of the chest. Lastly, it is remarked, that the symptoms of suffocation proceeding from inflammation of the lungs subside, or are evidently lessened by venesection, which is not the case when they depend upon an extravasation.

If it be true that some patients have had their breathing very little oppressed, notwithstanding an extravasation of blood in one of the cavities of the pleura, and that others have been able to lie with equal ease either on the sound or diseased side (see Thomson's Report, p. 87.), which is not common, we must conclude from these unusual cases, that we ought not to form our opinion from any one symptom in particular, but from the assemblage of a great many. Laffus, Pathol. Chir. tom. ii. p. 319.

On the subject of extravasations of blood in the thorax, the following are the sentiments of a distinguished writer: "Whatever may be the cause of this inward bleeding, the surgeon should attend to the following directions. He should first put his finger into the wound; perhaps it may discover the cause, or may evacuate the blood. If the blood do not follow the finger, then some tube must be introduced, and the tube for so simple an operation need not be a nice one. If he cannot get the tube into the thorax, and the breathing continue oppressed, he must enlarge the wound, and enlarge it freely. To be afraid of exposing the lungs to air when they are already torn with a bullet and loaded with blood is childish and useless theory, very unlike the proper management of such wounds. If the wound in the thorax be not too high above the third or fourth rib, and if no posture of the patient, however willing or able to turn himself, will bring the blood easily in that way, or if the wound be contused, oblique, and difficult to dilate, an operation must be performed, which, as it is commonly practised for pus in the breast, is called the operation of *Empyema* (see this word); that is, a very free incision must be made in the line betwixt two of the ribs; then the pleura must be punctured with a lancet, and a tube introduced. Or, in plain language, whenever it is found that the natural wound will not empty the thorax, a new wound should be made in what is called the chosen point, or the point of election, *i. e.* low, betwixt the seventh and eighth ribs, that there may be an easy flow. But whenever the wound is about the middle of the thorax, it should rather be dilated, which both changes the nature of the wound and gets out the blood. When this blood proceeds from a wound of the intercostal artery, such free incisions are the more necessary; they allow us to see the artery, to feel the jet of its warm blood by putting in the finger, and this allows us to press it with a compress, or tie it with the needle and thread." (See John Bell's Discourses on Wounds, p. 263, 264. edit. 3.) However, notwithstanding this author, and a few other surgeons thus talk of taking up the intercostal artery, we much doubt the possibility of the thing, nor do we know of any well-authenticated case on record where it has actually been done.

The propriety of some other parts of this advice is also questionable, especially that relating to thrusting tubes into the cavity of the thorax. The necessity of cutting into the chest at all in order to let out extravasated blood, in an early stage of a wound of the thorax, is positively denied by Scarpa, as we shall find from an extract we shall have to make from his work in speaking of wounds of the belly. On the contrary, Scarpa, Larrey, Assalini, Hennen, &c. all agree, that wounds of the chest should be closed, and superficially and lightly dressed. At all events, we may safely assert, that in these cases nothing but the urgency of the danger, unequivocally arising from the pressure of the mass of extravasated blood on the organs of respiration, can ever justify the practice of either making another opening into the chest, or of enlarging the original one. Of the method of keeping the wound open with tubes or tents, we have a very unfavourable opinion.

In every case of extravasation of blood in the chest, the discharge of it when respiration is dangerously oppressed is not the only indication. There is another one of at least equal importance: we allude to the adoption of a rigorous antiphlogistic treatment, in order to avert and diminish the dangers arising from inflammation of the pleura and lungs.

Besides extravasation of blood in the cavity of the pleura, there is another complication which sometimes attends wounds of the chest, and is particularly deserving of the attention of the practitioner. We mean the case of emphysema, or what Mr. John Bell calls "the tumour formed by air blown out from the lungs into the common cellular substance, or confined within the thorax, and oppressing the lungs." It is not, however, our wish to detain the reader long on this interesting disorder, because by turning to the article EMPHYSEMA, he will find a statement of all the principal knowledge which exists upon the subject.

Emphysema arises from the air escaping, first from the lungs into the thorax; then from the thorax through the wound in the pleura costalis into the cellular substance on the outside of the chest; and afterwards, the air inflates the cellular membrane over the whole body. As Mr. John Bell has related, emphysema is frequent after a fractured rib, because there is a wide laceration of the lungs, and no exit for the air; while it is less frequent in large wounds with a knife or broadsword, because in such cases the air has an open and unimpeded issue. It is very common after deep stabs with the bayonet or smallsword; and it sometimes arises in gun-shot wounds, though, as far as our experience extends, it is not so frequent in these particular instances, as Mr. John Bell describes. Mr. Hennen thinks it does not occur in more than one case out of fifty (p. 402.), which is, perhaps, a calculation considerably below the real state of things.

When the lungs are wounded, the air escapes from them at every inspiration into the cavity of the pleura, whence the next expiration it is compressed, and forced through the breach of continuity in the pleura into the cellular substance on the outside of the chest; for it cannot return into the wounded lung, because this is already full. Every new inspiration draws more air from the wounded lung, and every new expiration drives more air out into the cellular substance. There is no other outlet for the air, which spreads under the skin with wonderful rapidity. The emphysematous crackling tumour makes its first appearance over the broken rib, or over the wounded point of the thorax; it then extends over the whole chest, and next over the neck and face, filling particularly the eye-lids, so that the eyes are absolutely closed. It afterwards extends itself over the belly, down the thighs, and to the private parts, and no part escapes this tumour, except the palms of the hands and the soles of the feet. More air is every moment drawn out from the wound of the lungs, and driven under the skin; and the patient is every moment more and more oppressed, till at last the breathing is quite interrupted, the pulse flags, the extremities grow cold, and the patient, if he be not relieved by some operation, must die. John Bell, p. 267, 268.

The moment that the lungs are wounded, (says this author,) they fall down, and continue in this collapsed state until the wound heals, which it does in the course of a very few days; but from the moment in which lungs are wounded, the use of the wounded lobe is lost, so that if the wound be in the right side of the lungs, the breathing is performed entirely by the left; only half the quantity of air is inspired, and the breathing is difficult.

If the lungs, when wounded, were to continue in perpetual

tual motion, (says Mr. J. Bell,) I do not know how we should expect a cure; for the air would be continually streaming through the wound, and the wound itself alternately dilating and contracting, like that in an artery, could not heal. But as the wounded lung lies in a collapsed state, the edges of the wound are in contact with each other. P. 269.

That the lung of one side, which remains unhurt, is sufficient to support the system, we learn from various accidents; from those cases in which, either owing to the incisions made by the surgeon, or to the nature of the wound, the chest has been freely opened, the lungs of one side have collapsed, and yet the patient has lived with tolerable ease, and ultimately recovered. We learn it also from cases of emphysema, where the lungs are oppressed with air, and from cases of empyema, or pus, within the cavity of the chest, obstructing the expansion of the lungs. (See EMPYEMA.) And especially, (says Mr. J. Bell,) we are sure of it from the very gradual decay of those who die with large suppurations within the chest, in whom we find after death, that on one side there remains nothing but one small knob or tubercle of the lungs. Koelpen de Empyemate Obf. P. 135.

That the breathing should be easier in a free and open wound of the chest than in a punctured wound, or that in the case of a punctured wound the patient should be relieved by a free incision, no one need wonder; for in a punctured wound there is no way for the blood or air to escape from the thorax, while yet at every stroke of respiration, more and more blood and air is drawn out from the lungs, till at last the blood, and especially the air, are so condensed, that they not only oppress that side of the lungs, but by hindering the free play of the diaphragm, and loading the mediastinum, they oppress also the other lung, the difficulty of breathing increases, the extremities grow cold, and the patient dies.

Whatever danger then depends altogether upon emphysema itself depends upon the manner in which the confinement of air in the chest oppresses not only the wounded, but also the opposite lung, the diaphragm, &c. The extensive inflation of the cellular membrane in other parts of the body is a circumstance which creates a terrible disfigurement, but perhaps very little peril in itself. Sometimes, however, it proceeds to such a pitch, that even the interstitial cellular substance of the lungs themselves becomes inflated, and then suffocation is inevitable.

On the treatment of emphysema we shall merely remark at present, that the chief means, both of relieving the organs of respiration from compression, and of hindering the further increase of the diffusion of air in the cellular membrane, consists in practising an incision in the thorax at the part where the air first escapes from that cavity. For other practical observations we refer to the article EMPHYSEMA.

The existence of adhesions between the pleura costalis and pleura pulmonalis, previously to the receipt of a wound of the chest, must make an important difference with regard to the subsequent state of the lungs, and particularly with regard to their condition in the case of emphysema. Such adhesions must of course render a collapse of these organs impossible, and also prevent the air from insinuating itself between the surface of the lungs and the inside of the chest. Whether these occurrences can be perfectly prevented will of course depend upon the extent of the adhesions. They would, however, be certainly averted altogether, were the wound to happen just at a part of the chest where the pleura costalis and pleura pulmonalis happened to be adherent.

From some remarks which have been delivered, the reader will see, that wounds opening both cavities of the chest, unless

such adhesions exist, must produce immediate suffocation, in consequence of both lungs becoming collapsed. That this would really happen is the belief of the majority of the best modern writers, and there are several facts reported which tend to confirm the accuracy of the opinion. A late author, however, conceives, that the sinking of the lung is not an uniform consequence of a penetrating wound of the thorax. He observes, that we have sometimes ocular proof of this, not only by the close contact in which the lungs lie to the wound discoverable at first sight, but by protrusions which occasionally happen. From experiments on brutes, says he, we derive no satisfactory elucidation; for in some, where incisions on each side have been made through the intercostal muscles, much greater than the natural passage of the air, the lungs, so far from collapsing, have expanded again, the animal has lived, and in ten days run about as well as ever. And in our own species, the recoveries from wounds of the thorax on both sides, larger than the orifice of the glottis, dangerous as they are, are not few. Hennen's Obf. on Military Surgery, p. 404, 405.

Wounds of the heart generally prove immediately fatal, though it is true there are to be found in the records of surgery many curious exceptions to this observation. A soldier received the thrust of a sword, which entered one of the cavities of that organ, as was ascertained after death; yet he lived nine days after the accident. (Rhodius, Obf. Medic. centur. ii. obf. 39.) A young man, twenty-six years of age, was stabbed with a sword in the right side, between the third and fourth true ribs. He became exceedingly weak, had great difficulty of breathing, and died in four or five days. On opening the body, it was discovered that the heart had been completely transfixed, the weapon having passed from the right into the left ventricle, through the septum. The cavity of the chest was full of blood, and it was thought that the prolongation of life had been owing to the closure of the wound with coagula. (Saviard, obf. 113.) Haller, as Mr. Hennen observes, has recorded in his Bibliotheca Chirurgica, vol. ii. p. 378. an example in which a needle was found in the heart of an ox; and through the kindness of Mr. Hammick, surgeon of the royal naval hospital at Plymouth, Mr. Hennen was lately shewn a preparation, in which a pin was lodged in the human heart, but without any trace of the mode in which it got there. The patient had complained of a pain in his chest, about three months previously to his death, and died of carditis. (Obf. on Mil. Surgery, p. 429.) Ploucquet gives instances in which a ball was lodged in the heart of a stag, in the heart of a healthy dog, and in the anterior ventricle of the human heart, where it is stated to have remained for years. Another instance has also been recently published, in which a ball was found lodged in the right ventricle of the heart, near its apex, included in a great measure in the pericardium, and resting upon the septum. See the article *Cas Rares*, Dict. des Sciences Medicales.

Guattani mentions a case in which a patient lived eight years after a wound of the aorta (*De Aneurismatibus*); and in the Medical Records and Researches, 1798, is the extraordinary case of a penetrating wound, in which a bayonet passed through the colon, stomach, diaphragm, part of the lungs, and the right ventricle of the heart, and yet the patient survived the accident for upwards of nine hours. Mr. Hennen also refers to another instance, related by M. Chaiffenet, of a wound of the right ventricle, which did not prove fatal till the 15th day after the injury. (See Journ. de Med. Militaire, Paris, 1782, tom. ii. p. 359.) For additional observations on this subject, however, we must be content with referring to Mr. Hennen's publication.

WOUNDS.

As wounds of the diaphragm can hardly happen without the simultaneous injury of several other important parts, these cases must necessarily be attended with considerable danger; and indeed, when the tendinous centre of the diaphragm is injured, the accident is deemed by several writers of modern date as inevitably fatal. (Lassus, *Pathol. Chir.* tom. ii. p. 321. Callisen, *Syst. Chir. Hodiernæ, Pars ii.* p. 696.) The following are said to be usual symptoms of a wound of the diaphragm:—The patient is immediately seized with excessive anxiety and agitation. He feels acute pain in the hypochondria, and is obliged to keep himself bent forwards; and he is further afflicted with a cough, hiccough, convulsive spasms, and great difficulty of breathing. Delirium ensues, the muscles of the face are convulsed, the singultus grows worse and worse, and the case terminates fatally in the course of a few days.

Dangerous, however, as wounds of the diaphragm must generally be, on account of their being for the most part complicated with injury of some of the abdominal or thoracic viscera, there is no doubt that the danger has been exaggerated. “Wounds of the thorax (says Dr. Thomson) are not unfrequently complicated with wounds of the abdomen. In various instances of this kind (which this gentleman saw in the Netherlands after the battle of Waterloo), there existed undoubted proofs of the fact that wounds of the diaphragm are not necessarily fatal; for it must have been perforated once, if not twice, in several of the cases we saw, in which balls had passed across the lower part of the chest, and the same thing must have happened also, I conceive, in most of the cases in which the liver had been wounded. In one case, the ball had entered the right hypochondriac region, under the edge of the false ribs, and come out on the right side of the spine, on a level with the superior edge of the os ilium. This patient spit blood for some days, and voided it also by stool. On the examination after death of a patient who died thirty days after receiving the wound, and in whom a ball had entered the chest on the lower and outer part of the right papilla, and had come out of the abdomen on the left side of the umbilicus, the right lobe of the lung was found wounded, and the diaphragm and the upper part of the right lobe of the liver perforated. But neither in these cases, nor in several others of wounds of the diaphragm which we saw, did any peculiar symptoms, such as the risus sardonius, or convulsive motions of the chest, present themselves to our notice.” See Report of Obs. made in the Mil. Hospitals in Belgium, p. 93.

In the treatment of wounds of the diaphragm, abstractedly considered, very little can be done; bleeding and antiphlogistic remedies appear the only means which promise any effectual good. With these, however, we may sometimes usefully conjoin opiates.

Extensive wounds and lacerations of the diaphragm occasionally give rise to a particular and incurable species of rupture, in which some of the abdominal viscera form a protrusion in the cavity of the chest. This accident is termed a phrenic hernia, and some account of it will be found in the article **HERNIA**.

Wounds of the Belly, or Abdomen.—Wounds of the abdomen are divided into two principal classes: in one the solution of continuity is confined to the integuments, muscles, &c. exterior to the peritoneum; in the other this last membrane is penetrated, and frequently some of the viscera also which are included in it. Wounds affecting the parietes of the abdomen, but not extending through the peritoneum, whether of the punctured, incised, or contused kinds, have no essential difference from wounds of other parts, and the observations which have been offered on the subject of wounds

in general are in every respect applicable to all superficial wounds of the belly. It is worthy of remark, however, that the parietes of the abdomen are always weakened in consequence of wounds, and disposed to allow the viscera to form protrusions. Strong as the cicatrix may be, the point where it is situated continues subject to a hernia, which seldom fails to occur, unless the weakened part be properly supported with a belt or bandage. This accident may follow a simple punctured wound; but it invariably takes place in every instance where, in consequence of a severe contusion, the parietes of the abdomen have lost their tone, and yield to the impulse made against them by the parts which they contain. It was thus that a cooper's wife, whose history is given by Sennertus, after being violently struck on the abdomen by a piece of green elastic wood, which slipped out of her husband's hands, suffered such a relaxation of the contused part, that the anterior parietes of the abdomen yielded so as to form an enormous pouch, containing, during pregnancy, the gravid uterus itself.

After accomplishing the re-union of a superficial wound of the belly by means of an eligible position, adhesive plasters, and a bandage, we should therefore recommend the patient to wear a belt, or any other means of making pressure on the part which must be supported. Should the wound have been confined to the skin, however, and the muscles not have been at all divided, there would be no risk of a hernial protrusion afterwards, and of course the use of a belt, or any sort of bandage, would then be unnecessary.

If superficial wounds of the abdomen are unattended with any particular danger or peculiarity, the same observation cannot be made with respect to penetrating wounds, or those which pass through the peritoneum. We have seen that penetrating wounds of the chest give rise to a variety of dangers, sometimes depending upon the effusion of blood into the bronchiæ and air-cells of the lungs, or into the cavity of the pleura; sometimes upon the consequences of that extraordinary complication emphysema; but more especially upon the great tendency of the pleura and lungs to inflammation. The principal dangers of penetrating wounds of the belly arise also partly from internal hemorrhage within the cavity of the peritoneum; partly from the irritation which is produced by the occasional extravasation of the contents of the viscera; but in a still greater degree, from the strong disposition of the peritoneum to become affected with violent and extensive inflammation, in consequence of any injury or irritation. There are, says Mr. John Bell, a thousand occasions on which this delicacy of the peritoneum may be observed. The wound of the small sword, and the stab of the filetto, explain to us how quickly the peritoneum, and all its contained bowels, inflame from the most minute wound, although it be almost too small to be visible on the outside, and scarcely within; for, upon dissection, no intestines are seen wounded, and no feces have escaped into the abdomen. In those who die after lithotomy, we find the cavity of the peritoneum universally inflamed. The operation of Cæsarean section is fatal, not from any loss of blood, for there is little bleeding, nor from exposure to the air, for they also die in whom the womb bursts, and where the air is not allowed to enter; but merely from that inflammation which succeeds to wounds of the peritoneum, small as well as great, of which we have sometimes a melancholy proof in the operation of hernia, in which the stitching the wound, according to the whimsical improvement of some modern surgeons, or where the mere tying of the sac, as in the practice of the old rupture-doctors and castrators, often raised such inflammation as spread very quickly over the abdomen, and ended in gangrene.

grene. This inflammation may, no doubt, come on from the slightest scratch in the peritoneum itself; yet, in general, it arises rather from the wound of some of the viscera. If an intestine be wounded, it may pour out its feces into the abdomen; if the liver, spleen, or kidneys be wounded, these pour out blood; if the bladder, then the urine filters into the cavity of the belly. The extravasated food, feces, urine, blood, &c. act there as irritating extraneous substances, which no activity of the absorbents can remove, and which soon cause a fatal inflammation of every peritoneal surface within the abdomen. See John Bell's Discourses on the Nature and Cure of Wounds, p. 310. edit. 3.

Apprized by melancholy experience of the vast difference which the penetration of the peritoneum makes in the nature of a wound of the abdomen, surgeons have betrayed considerable anxiety to be able to ascertain at first, in every instance, whether the injury partakes of this serious description or not. But although the nature of the case is self-evident, when the wound in the parietes of the abdomen is large, and attended with protrusion of the viscera, it is often extremely difficult to judge whether the weapon has gone through the peritoneum or not, when the wound is a simple stab, unaccompanied with protrusion of the viscera, or with any effusion of their contents.

The generality of surgical authors have laid down a variety of criteria for determining the question, whether the case is a penetrating wound? Some of these writers lay much stress on comparing the direction of the wound with the natural thickness of the parietes of the abdomen at the injured part, and the breadth of the injury with that of the weapon. When the instrument has acted perpendicularly upon a point, where the parietes are thin, and the wound, though made with a narrowish weapon, like a sword, is yet of a certain breadth, there can indeed be little doubt of the case being a penetrating wound. But the impossibility of knowing in what direction the thrust has been made, and of procuring the weapon, in order to compare its diameter with that of the wound, generally renders this mode of discrimination useless in actual practice.

If a probe (say other writers) will readily enter perpendicularly to a certain depth, in a place where the parietes of the abdomen are thin, the circumstance is a proof that the case is a penetrating wound. But if the probe cannot be thus introduced, we are by no means justified in concluding that the wound does not penetrate. As the layers of muscles do not bear the same relative position to each other which they did at the time of the accident, they soon stop the passage of the probe; and in whatever posture we put the patient, it is next to impossible to put the parts exactly in the same position in which they were at the time of the receipt of the injury. Besides, when the wound is oblique, a probe which is not very flexible cannot easily be made to follow its track. The employment of this instrument is also not free from objections, founded on its creating pain and irritation, or even a renewal of hemorrhage and effusion of blood in the cellular membrane.

An absurd proposal has been made to inject a mucilaginous fluid into the wound, the passage of which into the belly would be a sure indication of the cavity of the abdomen being penetrated. It is obvious, however, that the injected liquid may not enter, though the case be a penetrating wound, owing to the change in the relative position of the layers of the abdominal muscles. The fluid may also continue in the wound in consequence of its passing into the cellular substance; and thus it may make the surgeon suppose that it enters the abdomen, when in reality it does not pass down even to the peritoneum. Nor can the mildest injection

be thus thrown into the cavity of the peritoneum without the utmost risk of exciting that fatal kind of inflammation which we have already mentioned, as the danger most to be dreaded in all wounds of the abdomen.

The signs then of a penetrating wound of the abdomen are fallacious, and the employment of such means as the probe and injections, with a view of ascertaining the real nature of the case, is not exempt from danger. Many spasmodic affections, which occasionally follow the receipt of a wound of the belly, are only equivocal, as they are sometimes owing entirely to the great sensibility of the patient. The protrusion of the abdominal viscera, and the discharge of fluids which they are known to contain, are the only sure signs of a penetrating wound. It is easily conceivable at the same time, that a wound may penetrate the cavity of the belly, and yet these symptoms may not occur, either because the external wound is too small to allow of the escape of any of the viscera or their contents, or because the weapon or ball, after piercing the peritoneum, has actually touched none of the bowels, or has merely glided over their surface. But penetrating wounds, which are unattended with protrusion of the viscera, or extravasation of any fluid in the cavity of the abdomen, are less alarming than several complicated wounds which do not penetrate. If in such case, says Richerand, the patient or bystanders were to inquire about the nature of the injury, we should avoid giving a positive opinion, informing them of the insufficiency of the means formerly practised, in order to ascertain the precise depth of the wound, and explaining the objections to the probe and injections. It should also be mentioned to them that the antiphlogistic treatment, which is the best in simple wounds which do not penetrate, is the only plan which could be adopted, were it certain that the injury had extended into the cavity of the abdomen. *Nosographie Chir.* tom. iii. p. 327—335. edit. 4.

In the following description of the treatment requisite for the different cases of penetrating wounds of the belly, we shall follow the order chosen by M. Richerand, and consider,

First, the cases in which the viscera, though uninjured, protrude at the wound.

Secondly, the cases which are complicated both with injury and protrusion of the viscera.

Thirdly, penetrating wounds unaccompanied with protrusion, but yet attended with injury of one or more of the viscera, as is indicated by particular symptoms, and especially by the issue of certain kinds of matter from the external wound.

And lastly, we shall conclude with noticing the subject of extravasations, and some wounds of particular organs and viscera.

1. *Of Wounds of the Belly, attended with Protrusion of the Viscera.*—When, in consequence of a division of the parietes of the abdomen by a cutting instrument, or their laceration by a bull's-horn, the intestines protrude between the lips of the wound, the first indication is to reduce the parts, and then to take measures for preventing a recurrence of the protrusion. The reduction is generally easy, if care be taken to relax the abdominal muscles by a judicious posture. In some cases, however, the wound is so narrow that the thing is more difficult, and here, instead of puncturing the bowel, in order to diminish its size by discharging the air which it contains, (as advised by many writers,) we decidedly recommend a moderate enlargement of the wound. This should be cautiously executed with a probe-pointed curved bistoury, introduced along the groove of a director; or, if there be room, under the guidance of the left finger.

finger. In this manner, and with due care, the wound may always be sufficiently dilated without the protruded parts being cut. Authors also recommend the incision for this purpose to be directed upwards; for (say they) the further the cut is from the lower part of the belly, the less liable will the patient afterwards be to hernia. The intestines should invariably be returned without delay, in every instance in which they are free from wound or gangrene. Should they even be slightly wounded or inflamed, no time should be lost in absurdly applying fomentations, &c. to them in their protruded state. The natural warmth and moisture of the cavity, into which they are to be replaced, will be far more congenial than any topical remedies. Should the parts, however, have any dirt or sand upon them, the most which ought to be done before their reduction is to wash them with warm milk and water.

The reduction having been effected, the patient is to lie upon his back, with the thighs bent upon the pelvis, and he must strictly avoid making any exertion, lest it bring on another protrusion. The wound is to be closed with adhesive plaster, and the uniting bandage; but if the wound should be large, and these means ineffectual, it would also be proper to employ sutures. The stitches, however, should always be as few as possible. This method of sewing up wounds of the belly made a long subject in all the old works on surgery, under the appellation of *Gastroraphe* (see that article); but at the present day, sutures are comparatively speaking almost rejected from practice, or are only employed when the opposite surfaces of wounds cannot be kept in contact without them. Nor are they then ever used, except the chance of union by the first intention still forms a temptation for the trial of the plan; for when a wound must heal by the granulating process, stitches can never be of the least utility.

When the omentum protrudes through a penetrating wound, and is strangulated by the narrowness of the opening, it soon contracts adhesions. Richerand recommends us to cut off all this membrane which exceeds the level of the integuments, and to leave in the wound the rest, which, he asserts, will act like a stopper, and hinder future herniæ. Were the wound, however, quite recent, so that adhesions could not yet have formed, the propriety of dilating the opening, and reducing the piece of omentum, would be unquestionable. Whenever, also, the omentum is found, and free from constriction, it should be reduced. In cases where a portion of this membrane is not only protruded, but gangrenous, writers authorize the excision of the dead part, and reducing the rest after the cut vessels have been tied singly with small silk ligatures. We apprehend, however, that in general, whenever the omentum has been out so long as to slough, adhesions within the wound have had time to form; an event which would embarrass the operator, and even render the safety and propriety of the attempt to reduce the living portion of the protruded membrane very questionable. Should the omentum, or intestine, however, be not adherent to the neck of the hernial sac, though gangrenous, (as occurred in an instance cited by Scarpa, *Traité des Hernies*, p. 268.) the propriety of trying to reduce it would be undeniable.

2. *Wounds of the Belly, with Injury and Protrusion of the Viscera.*—Penetrating wounds of the abdomen, attended with protrusion of the intestines, are always to be regarded as dangerous cases; but the danger is much more serious, if, besides being protruded, the bowels are also wounded. Under such circumstances, we have the authority of numerous writers on surgery, as a sanction of the practice of sewing together the edges of the division in the protruded

intestine; a practice, however, which, as we shall hereafter explain, does not meet with the approbation of that excellent modern surgeon, professor Scarpa, of Pavia. Every one, however, allows, that the attempt would be highly improper and rash, were the bowel only wounded, without forming a protrusion. It is this last occurrence which creates a material difference in estimating the possibility of the plan, the question of its necessity being at present excluded from consideration. When the parts are protruded, no enlargement of the external wound is necessary to render the application of a future practicable; the plan creates no disturbance and irritation of the peritoneum and contiguous viscera; there is no doubt concerning the actual existence of the injury, no difficulty in immediately finding out its precise situation.

But though many authors are so generally agreed about the propriety of using a suture in the case of a wounded and protruded bowel, they differ exceedingly, both as to the right object of the method, and the most advantageous mode of making the stitches. Some, having little apprehension of extravasation after the reduction of the gut, advise only one suture to be made, (frequently only through the mesentery,) and they employ the ligature chiefly with a view of confining the injured bowel near the external wound, so that whatever part of its contents may be effused, there will be a ready passage for the matter outward. Other writers wish to remove the possibility of extravasation, by applying numerous stitches, and attach little importance to the plan of using the ligature, principally for the purpose of keeping the intestine near the external wound.

When the wound of a bowel is so small that it is closed by the protrusion of the villous coat, the application of a suture must evidently be altogether needless; and since the ligature could not fail to cause irritation, as an extraneous substance, the employment of it ought unquestionably to be dispensed with.

Supposing, however, the breach in the intestine to be small, but yet sufficient to let the feces escape, what method ought to be adopted? The following practice has been tried. As Mr. A. Cooper was performing the operation for a strangulated hernia, at Guy's hospital, an aperture, giving issue to the intestinal contents, was discovered in a portion of the sound bowel, just when the part was about to be reduced. The operator, including the aperture in his forceps, caused a fine silk ligature to be carried beneath the point of the instrument, firmly tied upon the gut, and the ends cut off close to the intestine. The part was then replaced, and the patient did well. Mr. Travers, who has related this fact, approves of the plan of cutting away the extremities of the ligature, instead of leaving them hanging out of the external wound. It appears that when the first practice is followed, the remnant always finds its way into the intestine, and is discharged with the stools, without any inconvenience. But when the long ends are drawn through the outer wound, and left in it, they materially retard the process of healing. See Travers's *Inquiry into the Process of Nature in repairing Injuries of the Intestines*, &c. p. 112, 113.

Let us now inquire what ought to be the conduct of a surgeon, were he called to a patient, whose bowel is divided through its whole diameter, and protruded at the external wound? Various have been the schemes and proposals for the treatment of this sort of accident; and since experience has furnished few practitioners with an opportunity of seeing such a case in the human subject, a variety of experiments have been made on animals, in order to determine what treatment would be the most successful. Ramdohr, indeed,

WOUNDS.

is stated by Mœbius to have had occasion to try on the human subject a plan, on which a vast deal has been said and written. He cut off a large part of a mortified intestine, and joined the sound ends together, by inserting the upper within the lower one, and fixing them in this position with a suture; the ligature being also employed, to keep them at the same time near the external wound. The patient recovered, and the feces afterwards passed entirely by the rectum in the natural way. See Haller's Disputat. Anat. vol. vi. Obs. Med. Miscellan. 18.

About a year after the operation, the patient died, when the anatomical preparation of the parts was sent by Ramdohr to Heister. They were preserved in spirits of wine, and exhibited, according to this last author, an union of the two ends of the bowels together, and their consolidation with a part of the abdomen. Now it has been questioned by a late writer, whether the union here spoken of ever really happened. When the upper end of the bowel is introduced into the lower, the external surface of the former is put in contact with the inner one of the latter; a serous membrane is placed in contact with a mucous one. These heterogeneous structures, he alleges, are not disposed to unite. The mucous membrane, when inflamed, more readily secretes a kind of mucus, which must be an invincible obstacle to adhesion. He thinks it, therefore, more than probable, that, in the case related by Heister, the invagination was maintained by the union of the intestine with the corresponding part of the abdominal parietes. Several experiments on living animals have convinced him that this happens, and that the mucous membrane will not unite with the external peritoneal coat. This impossibility of producing an immediate union between mucous and serous membranes may, of course, be urged as an objection to Ramdohr's practice. (Richerand, Nosographie Chirurg. tom. iii. p. 344. edit. 4.) Another equally strong objection is, that the upper end of the bowel cannot be put into the lower one, unless it be separated from a part of the mesentery. Here the division of the mesenteric arteries may cause a dangerous bleeding. In vain did Boyer tie seven or eight of these vessels: his patient died with an extravasation in the abdomen. (Op. cit. tom. iii. p. 343.) Mœbius attempted to repeat Ramdohr's operation on a dog; but he could not succeed in insinuating the upper part of the divided bowel into the lower one, on account of the contraction of the two ends of the intestinal tube, and the smallness of the canal. Mœbius was, therefore, obliged to be content with merely bringing the ends of the bowel together with a suture: the animal died, however, of an extravasation of the feces.

Dr. Smith, of the Philadelphia Medical Society, also tried to repeat Ramdohr's method; but could not succeed. He divided the intestine of a dog transversely, and having inserted a piece of candle into that portion of the bowel which was supposed to be uppermost, he endeavoured to introduce the superior within the inferior; but the ends became so inverted, that it was found utterly impossible to succeed. The scheme was, therefore, given up, and only one suture made, the ligature being then attached to the external wound, in the manner advised by Mr. John Bell. The dog died, and on examination there was found a considerable quantity of feces and water in the abdominal cavity.

Two more trials were made of Mr. John Bell's plan by Dr. Smith, on the intestines of dogs: in both instances the animals died, the intestines being much inflamed, and feces effused in the abdomen. See Dr. Smith's Thesis.

Mr. Travers likewise tried the same experiment. "I

divided the small intestine of a dog, which had been for some hours fasting, and carried a fine suture through the everted edges, at the point opposite to their connection with the mesentery. The gut was then allowed to slip back, and the wound was closed. The animal survived only a few hours.—*Examination.* The peritoneum appeared highly inflamed. Adhesions were formed among the neighbouring folds, and lymph was deposited in masses upon the sides of the wounded gut. This presented two large circular orifices. Among the viscera were found a quantity of bilious fluid, and some extraneous substances, and a worm was depending from one of the apertures. By the artificial connection of the edges in a single point of their circumference, and their natural connection at the mesentery, they could recede only in the intervals, and here they had receded to the utmost." In another experiment, Mr. Travers increased the number of points of contact, by placing three single sutures upon a divided intestine, cutting away the threads, and returning the gut. The animal died on the second day.—*Examination.* Similar marks of inflammation presented themselves. The omentum was partially wrapped about the wound; but one of the spaces between the sutures was uncovered, and from this the intestinal fluids had escaped. On cautiously raising the adhering omentum, the remaining sutures came into view. Here again the retraction was considerable, and the intervening elliptical aperture proportionally large. On the side next to the peritoneum, however, the edges were in contact, and adhered, so as to unite the sections at an angle.

From such experiments, the conclusion drawn by Mr. Travers is, that apposition at a point or points is, as respects effusion, more disadvantageous than no apposition at all; for it admits of retraction, and prevents contraction, so that each suture becomes the extremity of an aperture, the area of which is determined by the distance of the sutures. (P. 116. 119.) This gentleman, therefore, maintains, that the absolute contact of the everted surfaces of a divided intestine, in their entire circumference, is requisite to secure the animal from the danger of abdominal effusion. (P. 121.) The species of suture employed, says Mr. Travers, is of secondary importance, if it secures this contact. (P. 134.) And, among other observations, we find, "wounds amounting to a direct division of the canal are irreparable, and, therefore, invariably fatal." P. 133.

In the Dictionary of Practical Surgery will be found several reasons for not entirely agreeing with these conclusions. We cannot admit that a total division of the intestinal tube is certainly and invariably fatal, because we must then not only disbelieve the mode of union in Ramdohr's case, which we undoubtedly do, but we must also disbelieve the result of that case, and of some others which we would cite, were this a publication expressly allotted to surgery. Nor are we at all convinced of the utility of applying numerous sutures to a divided bowel, in order to keep the edges of the wound together. Were a case to present itself to us, in which a bowel was protruded, and partly cut through, we should at most apply only a single suture, made with a common sewing-needle, and some fine silk; and even of the safety and utility of a single suture we entertain doubts. If the bowel were completely cut across; we would also attach its ends together merely by one suture of the same kind; and we should do so without feeling at all assured that the practice of a suture would be at all right. We perfectly coincide, however, with Mr. Travers respecting the advantage of cutting off the ends of the ligature, instead of leaving them in the wound, as we believe he is right in regard to the little chance there is of the injured intestine

testine receding far from the wound; and if the ends of the ligature are then of no use in keeping the bowel in this position, they must be objectionable as extraneous substances. *Dict. of Pract. Surgery*, edit. 3. art. *Wounds*.

The following is the process by which, according to Mr. Travers, a divided intestine is healed, when sutures are employed: "It commences with the agglutination of the contiguous mucous surfaces, probably by the exudation of a fluid, similar to that which glues together the sides of a recent flesh wound, when supported in contact. The adhesive inflammation supervenes, and binds down the everted edges of the peritoneal coat, from the whole circumference of which a layer of coagulable lymph is effused, so as to envelope the wounded bowel. The action of the longitudinal fibres being opposed to the artificial connection, the sections mutually recede, as the sutures loosen by the process of ulcerative absorption. During this time, the lymph deposited becomes organized, by which further retraction is prevented, and the original cylinder, with the threads attached to it, is encompassed by the new tunic.

"The gut ulcerates at the points of the ligatures, and these fall into its canal. The fissures left by the ligatures are gradually healed up; but the opposed villous surfaces, so far as my observation goes, neither adhere nor become consolidated by granulation, so that the interstice, making the division internally, is probably never obliterated." *Travers on Injuries of the Intestine*, &c. p. 128.

The celebrated Scarpa published, a few years ago, some highly interesting remarks on the process employed by nature in repairing solutions of continuity in the intestinal canal, especially in cases of hernia with gangrene; and the results of his investigations are also both curious and instructive, in relation to what happens, and what ought to be done, in wounds of the abdomen. (*Sull'ernie Memorie Anatomico-Chirurgiche*, &c. Milano, 1809.) He observes, that the least fatal consequence of a mortification of the bowel is the escape of the excrement through the wound, or *artificial anus*; an afflicting and disgusting infirmity, but one which does not preclude all hope of a radical cure, even though a considerable portion of the intestinal canal may have been destroyed by sphacelus. The recorded examples of such cures are abundant, and yet, says Scarpa, nothing has yet been written which will serve to convey an exact idea of the simple and admirable means which nature employs in accomplishing them. Surgeons generally suppose, that after the detachment of the dead parts, the two orifices of the bowel remain gaping, and acquire adhesions to the margins of the external wound; that afterwards, in proportion as this contracts, they come gradually nearer together, and in the end touch each other so accurately, that the feces are capable of passing directly from the superior into the inferior portion of the gut. But this theory cannot satisfy those who have attentively examined, in some cases of mortified herniæ, the respective situation of the two orifices of the intestine, and their relation to the external wound. In fact, the two ends of the bowel are constantly found lying in a parallel manner by the side of each other: the upper with its orifice open, and directed towards the external wound by the feces which issue from it; the lower, on the contrary, as it gives passage to nothing, always has a tendency to become less capacious, and retracted into the cavity of the abdomen. The contraction of the external wound cannot have the least effect in changing the direction of these two orifices, nor consequently in applying them to each other. Even supposing there were some natural tendency to this approximation, the upper orifice, being wider than in the natural state, and directed outwards,

could never accurately coalesce with the lower one, which is shrunk, and retracted within the belly. The feces then could never pass from one into the other without the effusion of a large part of them outwardly, and an incurable fistula, discharging the intestinal contents, would in every instance be the consequence.

Scarpa had an opportunity of examining the body of a young man, who, in consequence of eating a large quantity of indigestible food, died about ten months after having been operated upon for a congenital hernia, attended with mortification of the protruded bowels, at a period when he had recovered, with the exception of an occasional discharge of a very small quantity of feces from an inconsiderable fistulous opening. He also dissected two other cases. From all these it appears, that the breach in the intestinal canal is not repaired by the orifices of the upper and lower portions of the bowel re-uniting, coalescing, and running as it were into each other; nay, that they meet at a very acute angle, the axis of one not corresponding with that of the other, and they never lie laterally together. On the contrary, Scarpa's investigations satisfactorily prove, that a funnel-shaped membranous canal (what he terms the *imbuto membranoso*), composed of the remains of the hernial sac, constitutes the medium of communication between the upper and lower orifices of the bowel, which, in an early stage of the case, becomes adherent to the peritoneum about the neck of the hernial sac. The base of the funnel-shaped membranous cavity corresponds to the bowel, and its apex tends towards the wound or fistula. It farther appears, that the feces, in order to get from the upper into the lower part of the bowel, have to pass through the funnel-shaped cavity in quite a femicircular track, and that between the orifices of the bowel, directly opposite to the aperture between the cavity of the intestine and that of the funnel-shaped membrane, a considerable projection or jutting angle is formed, which makes a material additional obstacle to the direct passage of the feces, from the upper into the lower portion of the intestinal tube.

Scarpa thus explains the formation of the funnel-shaped membranous cavity, that constitutes the channel of communication betwixt one part of the bowel and the other: "The hernial sac, as every surgeon knows, does not always partake of gangrene with the viscera contained in a hernia: and even when it does slough, since the separation of the dead parts happens on the outside of the abdominal ring, there almost always remains in this situation a portion of the neck of the hernial sac perfectly found. We may say, therefore, that in all cases immediately after the detachment of the mortified intestine, whether it happen within or on the outside of the ring, the two orifices of the gut are enveloped in the neck of the hernial sac, which soon becoming adherent to them by the effect of inflammation, serves for a certain time to direct the feces towards the external wound, and to prevent their effusion in the abdomen. In proportion as the outer wound diminishes, the external portion of the neck of the hernial sac also contracts; but that part which embraces the orifices of the intestine gradually becomes larger, and at length forms a kind of membranous funnel or intermediate cavity, which makes the communication between the two parts of the bowel. This adhesion of the neck of the hernial sac round the two orifices of the gut does not hinder the latter from gradually quitting the ring, and becoming more and more deeply placed in the cavity of the abdomen." Scarpa then cautions surgeons not to fancy from this account, that there is any occasion to pass a ligature through the mesentery for the purpose of fixing it near the ring, even were the gan-
grenous

grous bowel perfectly free and inadherent to the neighbouring parts. The truth is, that the adhesive inflammation, which also commences immediately after the operation, fixes the parts near the wound before they can be drawn away by any retraction of the bowel or mesentery; and in the course of the first 24 hours the two orifices of the divided intestine are constantly enveloped in the remains of the hernial sac. In a case of this kind, where the mortified bowel was not at all adherent to the neck of the hernial sac, Scarpa introduced a ligature through the mesentery in the usual way, and on withdrawing it at the end of 24 hours, and passing his finger to the bottom of the wound, he found the circumference of the two orifices of the bowel every where adherent. When a ligature through the mesentery had not been practised, and no effusion, he also invariably discovered the bowel adherent to the neck of the hernial sac, in every subject who had died soon after the operation for a strangulated hernia, complicated with gangrene, and whom he examined after death. Certainly, he observes, it must be allowed that the orifices of the divided intestine do retract, and become farther from the ring; but they do so very slowly, and always draw along with them the neck of the hernial sac to which they contract early adhesions.

Our limits oblige us to pass over many other interesting observations relative to the causes which facilitate or retard the re-establishment of the continuity of the intestinal canal, and on the necessity of the funnel-shaped membrane as a substitute for the portion of bowel destroyed by gangrene. We shall next notice the comparison of the artificial anus, arising from a mortified hernia, with that which is the result of a penetrating wound of the abdomen, as made by the intelligent Scarpa. "Why," he inquires, "is it so common to see the continuity of the intestinal canal re-established after a mortified inguinal or crural hernia, while the artificial anus is always incurable, when it is formed in consequence of a penetrating wound of the abdomen with protrusion of the intestine, whether a part of the canal be destroyed by gangrene, as in the instance related by Moscati (Mém. de l'Acad. de Chir. t. 8.), or whether it be totally or partially divided by the wounding instrument, as in the examples recorded by Stalpart-Wander Wiel (Obf. Rar. t. ii. obs. 25.), Cabrole (Oper. Med. obs. 13.), Fabricius Hildanus (Centur. i. obs. 74.), &c.?" Scarpa will not even allow as an exception to this remark the case recited in the 2d vol. of the *Œuvres Chir. de Desault*; because he conceives the details are not sufficiently explicit.

In order to resolve this problem, says he, we have only to compare a wound of the belly complicated with protrusion and mortification of the bowel, with a mortified intestinal hernia, and draw a parallel between the circumstances which accompany the two cases, and constitute their chief differences. 1st, In a hernia, the two extremities of the mortified gut are always enveloped in the remains of the hernial sac, which form in front of the two orifices a kind of funnel-shaped canal. There is nothing like this at the extremities of a bowel divided either by a cutting instrument which has penetrated the abdomen, or by mortification, which has complicated a wound of this description. 2dly, In these last instances, the wounded or burst intestine becomes adherent to the edges of the external wound; consequently, it cannot retract into the abdomen, and the feces, which descend out of the upper portion, being as it were on a level with the skin, must necessarily all escape out of the external wound. This is precisely what actually happens, it being known that artificial ani of this kind are always incurable. After a mortified hernia, on the contrary, it is upon the facility with which the bowel becomes situated farther

from the wound, drawing along with it the remains of the hernial sac, that the formation of an intermediate cavity between the two orifices of the gut depends, and which is to make the communication between them. What happens after penetrating wounds of the belly, with injury of the bowels, is also seen in ventral herniæ, which have formed under the cicatrix of a long-cured wound of the abdomen, when such herniæ are unfortunately attacked by mortification. Large, old, umbilical, and ventral herniæ, though furnished with a hernial sac, generally give rise to incurable artificial ani whenever they slough. Scarpa explains the cause of this circumstance, by adverting to the very intimate adhesion which exists in such herniæ between the sac and the aponeuroses and integuments of the abdomen, and which tends to hinder the formation of the funnel-shaped membranous cavity in front of the orifices of the intestine, and which alone can establish a communication between them.

It follows, says Scarpa, from the foregoing and other facts, that the retraction of the neck of the hernial sac, and of the two orifices of the bowel, is essential to the re-establishment of the continuity of the intestinal canal, when a breach has been made in it by mortification. Hence, he thinks, that in future every body will consider the plan of passing a ligature through the mesentery, in order to keep the two ends of the gut near the outer wound, not only as useless, but even as dangerous. The adhesions of the neck of the hernial sac to the intestine, before the occurrence of gangrene, must almost always render the ligature useless. And even when the adhesion does not exist at the period of cutting through the sloughs, Scarpa asserts that the ligature is equally unnecessary. Indeed, says he, immediately after the operation, while nature is effecting the separation of the dead from the living parts, the latter invariably contract, in a very short time, close adhesions to the neck of the hernial sac, either on a level with a ring, or a little within it, and there is no danger of the feces being extravasated in the abdomen. If the latter accident has sometimes happened in subjects who have died of hernia with gangrene in a few days, it has been because the feces could not make their way outward quick enough, and therefore occasioned a bursting of the bowel in the abdomen, within the ring and beyond the extent of the hernial sac. If, in some other cases, the two orifices of the bowel have been found in the dead subject not adherent to the neck of the hernial sac, and the feces extravasated, Scarpa thinks it has happened only after death, when the relaxation of the whole abdomen has let the ends of the bowel quit the neck of the hernial sac, to which it had not yet acquired any adhesions. But he conceives that nothing like this can ever happen in the living body, owing to the alternate action of the diaphragm and abdominal muscles, which compress all the viscera, and tend to propel them outward.

Hippocrates writes, "Si quod intestinorum gracilium discinditur, non coalescit." (Sect. 4. Aphor. 24.) This aphorism, says Scarpa, taken in its true sense, is the expression of an incontestible fact. It is very true, that wounds of the intestinal canal follow in their cicatrization quite a different course from simple wounds of the skin, muscles, or any other parts of the body. Their edges are never observed to become immediately applied to each other, and therefore, strictly speaking, they do not re-unite. Their cure is altogether completed through the medium of the surrounding parts; that is to say, by the adhesions which the intestines contract with the great sac of the peritoneum lining the parietes of the abdomen, or with the productions of this membrane which compose the external covering

covering of the greater part of the viscera. Littre relates, that a lunatic stabbed himself with a knife in eighteen places about the abdomen, eight of which wounds penetrated into this cavity, and evidently injured the bowels. The man, however, recovered in two months; but in another paroxysm of mania he threw himself out of the window, and was killed. On opening his body, all the cicatrices of the intestinal canal were found adherent to some point of the surface of the adjacent viscera or parietes of the abdomen. There was not a single one which seemed to be formed by the direct contact of the edges of the intestinal wound with each other. Acad. Roy. des Sciences de Paris, 1705.

The peritoneum, when irritated by any cause whatsoever, has a singular disposition to inflame round the point of irritation, and to contract adhesions with the parts which are contiguous to it in the same situation. Thus, when one or several convolutions of intestines have been divided by a cutting instrument, or pierced by a ball, they always become united for a certain extent to the surrounding parts, all of which are covered with the peritoneum. (See also Platner's *Instit. Chir.* § 694.) These adhesions, which are the only means employed by nature for blocking up accidental openings in the intestinal canal, are promoted by the pressure which the abdominal muscles and diaphragm alternately make upon the viscera in the actions of inspiration and expiration.

In a subsequent part of his work, Scarpa delivers his own sentiments on the different plans which have been proposed for effecting the re-union of a divided intestine. If, says he, we compare Ramdohr's operation with the simple and effectual processes employed by nature for re-establishing the continuity of the intestinal canal after herniæ with mortification, we are compelled to acknowledge on this point, as well as on many others, that art continues very inferior to nature.

In the first place, says Scarpa, the introduction of one part of the bowel into the other is impracticable in a great many cases of mortified herniæ, in consequence of the adhesions which the sound part of the intestine has contracted with the neck of the hernial sac, during the inflammatory period of the strangulation. Secondly, it is hardly ever possible, without inconvenience, to draw a considerable portion of the intestinal canal out of the belly, for the purpose of introducing, with all the requisite precautions, the upper end of the bowel into the lower. This cannot be done without handling for too long a time, and more or less roughly, the bowel, which is already irritated; which circumstance, together with the pricks of the needle, and the dragging of the stitches, is more than an adequate cause for the production of a fatal inflammation. The danger will be still farther increased, if, according to the experiments of some modern surgeons, the two ends of the bowel are sewed together over a piece of a calf's trachea, or a small hollow cylinder of tallow, or isinglass, a pasteboard tube, &c. Whatever may be the foreign body put within the bowel, it may, by obstructing the course of the feces, bring on violent inflammatory symptoms, and destroy the patient in the most agonizing sufferings.

Scarpa then adverts to the experiments made on dogs by Dr. Thomson of Edinburgh, and Dr. Smith of Philadelphia, which tend to prove that the two extremities of a divided bowel may be united by means of a future, and then returned into the cavity of the belly, without endangering the animal's life. (See also Boyer's experiments on this subject, in the *Mém. de la Société de Médecine de Paris*, tom. i.) It is alleged (says Scarpa), that there is no risk of the ligatures falling into the cavity of the abdomen after

their detachment; but that by one of the operations of nature which cannot be explained, the threads are voided with the feces after the cure. Scarpa notices that the particulars of the way in which these futures were made is not given; and how (says he) have the above gentlemen succeeded in applying the orifices of the divided bowel accurately to each other, which is extremely difficult, especially in dogs? In whatever light the subject is viewed (he observes), "I doubt whether it be possible to re-unite, by means of any future, the extremities of a divided bowel after mortification in hernia, or at least to do it with any probability of success. Such experiments, even when they succeed in the best possible manner, merely prove that certain operations, which would most frequently be useless or fatal on man, may be successfully practised on other animals."

On the contrary (says Scarpa), in the circumstances which have been supposed, nature is daily observed to succeed in re-establishing the continuity of the intestinal canal, by means equally simple and mild. She prepares herself (as it were) for this work before gangrene actually takes place, by forming adhesions between the strangulated bowel and the neck of the hernial sac. After the separation of the mortified parts, she draws back into the abdomen the extremities of the divided bowel, and out of the remains of the hernial sac, she forms a sort of funnel-shaped membrane, which serves at first for directing the feces outwards, and afterwards for transmitting them from the upper orifice of the intestine into the lower, by making them follow a semi-circular track from before backwards. For two or three instances of the complete success of Ramdohr's operation, an almost innumerable multitude of cures effected altogether by the powers of nature could now be cited. Thus, says Scarpa, in the present state of our knowledge, we should congratulate patients who, in these unfortunate circumstances, fall into the hands of surgeons either incapable of undertaking an operation, or little solicitous about healing up the wound.

It may perhaps be imagined (continues Scarpa), that Ramdohr's operation is better calculated for certain cases of penetrating wounds of the abdomen, as, for instance, where the intestine has been completely divided with a cutting instrument, or by the effects of gangrene arising from long exposure to the air. Scarpa here allows that it would be very desirable to find out some operation which could be useful in these circumstances, which are the more unfortunate, because they do not furnish nature with the means of re-establishing the continuity of the intestinal canal, as in cases of mortified herniæ. But he doubts whether in such instances Ramdohr's operation could be undertaken with any probability of success; for the complete division of the intestine is almost always the result of an enormous wound, which having interested several viscera leaves little or no hope of recovery. Supposing the bowel should not have been divided with the cutting instrument, but that it is protruded and gangrenous from long exposure, it must be remembered, that in this case it will have contracted adhesions to the lips of the wound, even before the separation of the mortified part; consequently, the bowel cannot be drawn farther out of the belly, so as to allow one end of it being introduced into the other. To undertake such an operation then, would be to expose the patient to much greater perils than that of an incurable artificial anus.

According to Scarpa, it is little to have proved that Ramdohr's operation is impracticable when the intestine has been completely divided; he proceeds farther, and has no hesitation in asserting, that *in all cases of penetrating wounds*

of the abdomen, attended with injury of the intestine, whether the canal be opened longitudinally or transversely, a future is always an operation not merely useless, but even dangerous and fatal. In whatever manner it is practised, one cannot avoid the evils which must originate from the punctures, however few, and from the passage of the ligatures through the coats of the intestine; a part endued with exquisite sensibility, and whose external tunic is much disposed to inflame, and rapidly to communicate the inflammation to all the other abdominal viscera. It has been unfortunately proved, by the experience of several ages, that in most of the cases in which the intestine has been stitched in penetrating wounds of the belly, the patients have died in the greatest agony. If a few have escaped the dangers of this operation, it has been because in them the stitches soon cut their way out, and were voided with the feces which continued to escape from the wound until it was entirely healed.

All surgeons of experience, and particularly those of large hospitals, have often seen wounds of the right or left iliac region accompanied with injury of the great intestine. They may also have noticed, in these examples, that after the subsidence of the local and general inflammatory symptoms, the wound still continues to discharge the feces for a certain time; but that afterwards it contracts, and the excrement resumes its usual course. These wounds almost always heal completely: first, because the adhesion of the large intestine to the parietes of the abdomen prevents the feces from being extravasated in the cavity of the peritoneum; and secondly, because the ample capacity of the same bowel always presents a ready passage for the feces, notwithstanding the progressive and sometimes quick closure of the external opening.

If, in the instance of a penetrating wound of the belly attended with a wound of the small intestines, it were in the surgeon's power (as indeed it is) to return the bowel into the abdomen, so that the opening in it may exactly correspond with the wound in the abdominal parietes, there could not be a doubt of its quickly acquiring adhesions to the peritoneum, which lines the part around the internal orifice of the external wound: hence the feces would readily escape through the outer wound, and at length it would happen, after a certain time, as in wounds of the large intestines, that the artificial anus would gradually close up, and the feces resume their natural track. The narrow diameter of the small intestines would not make an insurmountable obstacle to the passage of the feces, provided they be, as they usually are in this portion of the intestinal canal, sufficiently fluid; and besides (says Scarpa) is it not proved by experience, that they resume their natural course, after the cure of an artificial anus, even when a considerable noose of the small intestines has been destroyed by gangrene, and when the two ends form by their re-union a very acute angle? In all cases, the patient's life would be saved, and the worst that could happen would be his being afflicted the rest of his days with a fistula discharging feces.

Encouraged by these principles, which are the natural deductions of a comparison of wounds of the large intestines with those of the small ones, Scarpa feels no hesitation in admitting the possibility of curing the latter, without having recourse to a future. He observes, that it would not be difficult for him to quote examples of such cures. Amongst others, he has lately seen one which deserves to be mentioned here. A portion of small intestine, protruded through a penetrating wound of the abdomen, happened to be punctured with a bodkin by a country surgeon, in his endeavours to return the part into the belly. The feces, however, were not extravasated in the cavity of the peri-

toneum, but were for a long while discharged through the wound. The opening in the bowel always corresponded exactly to that in the parietes of the abdomen, although no future was practised, nor any ligature put through the mesentery in order to keep it in this situation. The feces afterwards gradually resumed their natural course, the wound at the same time became smaller, and in the end healed up. The young man, the subject of this case, now enjoys very good health, and suffers no inconvenience which can justify a suspicion of any obstruction in the passage of the feces.

The incessant pressure made by the abdominal muscles and diaphragm upon all the viscera, is a cause why the wounded intestine, instead of quitting the external wound, enters it, and contracts adhesions to its lips. If, however, a too timorous surgeon were afraid of entirely trusting, on this point, to the wise providence of nature, he might (Scarpa thinks) without inconvenience pass a ligature through the mesentery, behind the portion of wounded bowel, as is usually and quite unnecessarily done in cases of mortified hernia. Forty-eight hours, or thereabouts, would be time enough for the intestine to contract adhesions, through the medium of the peritoneum, to the inner edges of the wound. After this period, the ligature would be completely useless, and it ought to be withdrawn, as there would now be no chance of extravasation of the feces in the belly. At the same time one should neglect no remedies, internal as well as external, which may be of use in moderating the patient's sufferings, diminishing the energy of the circulation, and bringing the inflammation down to the degree requisite for the formation of adhesions. One ought also to keep open the external wound with the same precautions, and according to the same indications which are to be attended to in the treatment of an artificial anus. The principal object of these precautions is, to let the treatment be such that the wound may only diminish in proportion as the evacuation from the lower part of the intestinal canal increases.

Here it may be *à propos* to observe, that the conduct of a surgeon in the treatment of penetrating wounds of the abdomen, attended with injury of the small intestines, is exactly the reverse of what it ought to be in the treatment of penetrating wounds of the chest, accompanied with injury of the lungs.

In the latter, says Scarpa, physiology, agreeing with experience, teaches us that no means should be omitted for effecting the immediate union of the wound, (as it is termed, *by the first intention*;) care being taken to check the force of the circulation by repeated bleedings and every antiphlogistic remedy, in order to prevent or diminish, as much as possible, internal hemorrhage. If, notwithstanding all these means, blood should be extravasated between the pleura and lungs, it presses equally upon every point of these viscera, resists their motion, and thereby contributes to stop the bleeding. If, after the wound in the lungs is healed, the extravasated blood be not in too large quantity, it will be gradually removed by the absorbents. In the contrary case, it will form a swelling beneath the external cicatrix, and present itself externally (see Discours sur les Principales Maladies observées à l'Hôtel Dieu de Lyon, &c. par M. Petit, p. 299.); or else a counter opening must be practised at the inferior part of the chest. See ΕΜΠΥΕΜΑ.

We are to act quite differently in the treatment of a penetrating wound of the belly, with protrusion and injury of the intestine; for in this case, the chief indication, that on which the patient's safety mainly depends, consists in keeping the external wound open, in order that the feces may find a ready outlet. The wounded bowel soon contracts

adhesions to the inner lips of the wound of the belly, and then we have nothing to fear from an extravasation of the intestinal matter in the cavity of the peritoneum. Afterwards, in proportion as the feces resume their natural course, the external wound is to be allowed to diminish, and entirely heal up. See Scarpa Sull'ernie Memorie Anatomico-Chirurgiche, &c. mem. 4.

In every instance in which the abdomen has received a penetrating wound, attended with injury and protrusion of a portion of the intestinal canal, the displaced part is to be reduced, whether it be stitched or not. This should be accomplished as speedily as possible, before the bowel has suffered much from exposure, constriction, &c. and also before any adhesions have formed at the inner orifice of the external wound; adhesions which would render the reduction of the protruded part impracticable. Of course, if the wound should be too small to admit of the reduction being effected without handling and bruising the bowel immoderately, it ought to be carefully enlarged with a curved bistoury, guided on a director. Indeed, according to Scarpa's principles, one would suppose that in every case of this kind the wound, if not free, should be dilated, as by this means the issue externally of whatever escapes from the breach in the intestine after its reduction would be facilitated. The rest of the treatment consists in the rigorous adoption of antiphlogistic measures, more especially a low diet, and copious and repeated venesections, with a view of counteracting the danger of peritoneal inflammation. With respect to the dressings, they cannot be too simple, and they ought always to be light and superficial. A pledget of any common unirritating ointment is all that is requisite, and it must be renewed as frequently as the quantity of the discharge, &c. from the wound may render necessary.

3. *Penetrating Wounds of the Belly, attended with Injury of the Bowels, but with no Protrusion.*—A wound of the intestines is indicated by the discharge of blood with the stools, and sometimes by the escape of fetid air, or of intestinal matter from the external wound. Such an injury, however, when the wounded bowels lie concealed in the belly, does not always admit of being known with certainty immediately after occurrence. In the majority of examples, there is at first no escape either of air, or of the contents of the bowels, from the external wound; the quantity of blood voided per anum may be inconsiderable, and of course none at all will generally be discharged for some time after the accident. Wounds of the small intestines, especially of the duodenum and jejunum, are indeed usually followed by great anxiety, paleness of the countenance, syncope, cold perspirations, a small intermitting tremulous pulse; but then these symptoms are only equivocal, and furnish no positive information, because several of them may happen in nervous subjects, from a mere superficial unimportant cut or stab. Our inability, however, to say assuredly, in every case, whether the bowels are injured or not, is a thing of no practical importance; because when the nature of the accident is not clearly manifested by some peculiarity or severity of the symptoms, the case should invariably be treated on common, simple, antiphlogistic principles; and also, when circumstances leave not the smallest doubt of the intestines being hurt, the same treatment is the only rational one which can be pursued. Wounds of the small intestines are reckoned much more dangerous than those of the large; and the nearer the injury is to the pylorus, the greater, generally speaking, is the degree of danger. Such cases are also much more frequently, than injuries of the large intestines, the cause of extravasation. In the latter examples, the symptoms are commonly milder, and either the passage

of the intestinal contents outward through the wound more easy and certain, on account of the bowel being naturally less moveable than the other intestines; or their passage in their natural course more ready, by reason of the greater capacity of that part of the intestinal tube.

A wounded intestine is said to present some particular appearances, to which the generality of writers have paid no attention. "If a gut be punctured, the elasticity of the peritoneum, and the contraction of the muscular fibres, open the wound; and the villous or mucous coat forms a sort of hernial protrusion, and obliterates the aperture. If an incised wound be made, the edges are drawn asunder and reverted, so that the mucous coat is elevated in the form of a fleshy lip. If the section be transverse, the lip is broad and bulbous, and acquires tumefaction and redness from the contraction of the circular fibres behind it, which produces, relatively to the everted portion, the appearance of a cervix. If the incision is according to the length of the cylinder, the lip is narrow, and the contraction of the adjacent longitudinal, resisting that of the circular fibres, gives the orifice an oval form. This eversion and contraction are produced by that series of motions, which constitutes the peristaltic action of the intestines." Travers on Injuries of the Intestines, p. 85.

According to this gentleman, some of these appearances were described by Haller, in *Element. Physiol. lib. 24. sect. 2.* and *Opera Minora, tom. i. sect. 15.*

Having witnessed the facility with which considerable injuries of the intestinal tube were repaired, Mr. Travers was desirous of ascertaining more fully the powers of nature in the process of spontaneous reparation, and of determining under how great a degree of injury it would commence, as well as the mode of its accomplishment. For these purposes, he divided the small intestine of several dogs as far as the mesentery. All these animals died, in consequence of the intestinal matter being extravasated, if they had been lately fed, or if they had been fasting in consequence of inflammation, attended with a separation of the ends of the divided bowel, eversion of the mucous coat, and obliteration of the cavity, partly by this eversion, and partly by a plug of coagulated chyle.

In one particular instance in which Mr. Travers made a division of the bowel half through its diameter, a sort of pouch was formed round the injured intestine. "A pouch, resembling somewhat the diverticulum in these animals, was formed opposite to the external wound, on the side of the parietes, by the lining peritoneum; on the other side, by the mesentery of the injured intestine, that intestine itself, and an adjacent fold, which had contracted with it a close adhesion. The pouch, thus formed and insulated, included the opposed sections of the gut, and had received its contents, &c. The tube at the orifices was narrowed by the half eversion, but offered no impediment to the passage of fluids." (P. 96.) Whether, under these circumstances, the functions of the alimentary canal could have been continued, Mr. Travers professes himself incapable of deciding. Among the inferences which this gentleman has drawn from the experiments detailed in his publication, the tendency of the two portions of a divided bowel to recede from each other, instead of coalescing to repair the injury, merits notice, inasmuch as it tends to shew that the only means of spontaneous reparation consist in the formation of an adventitious canal, by the encircling bowels and their appendages. The everted mucous coat, which is the part opposed to the surrounding peritoneum, is also indisposed to the adhesive inflammation.

When, however, the wound of the intestine is smaller,

the obstacles to reparation are not absolutely insurmountable. Here retraction is prevented, and the processes of eversion and contraction modified by the limited extent of the injury. If, therefore, the adhesive inflammation unite the contiguous surfaces, effusion will be prevented, and the animal escape immediate destruction. But union can only take place through the medium of the surrounding parts.

According to Mr. Travers, it is the retraction immediately following the wound that is a chief obstacle to the reparation of the injury; for if the division be performed in such a way as to prevent retraction, the canal will be restored in so short a time, as but slightly to interrupt the digestive function. In confirmation of this statement, a ligature was tightly applied round the duodenum of a dog, which became ill, but entirely recovered, and was killed. "A ligature, fastened around the intestine, divides the interior coats of the gut, in this effect resembling the operation of a ligature upon an artery. The peritoneal tunic alone maintains its integrity. The inflammation, which the ligature induces on either side of it, is terminated by the deposition of a coat of lymph, which is exterior to the ligature, and quickly becomes organized. When the ligature, thus enclosed, is liberated by the ulcerative process, it falls of necessity into the canal, and passes off with its contents." P. 103, 104.

It appears also from Mr. Travers's experiments and observations, that longitudinal wounds of the bowels are more easily repaired than such as are transverse. In a dog, a longitudinal wound, of the extent of an inch and a half, was repaired by the adhesive inflammation. Here the process of eversion is very limited; the aperture bears a smaller proportion to the cylinder of the bowel; and the entire longitudinal fibres resist the action of the circular, which are divided, and can now only slightly lessen the area of the canal. P. 108.

When the wounded bowel lies within the cavity of the abdomen, no surgeon of the present day would have the rashness to think of attempting to expose the injured intestine, for the purpose of sewing up the breach of continuity in it. In fact, the surgeon seldom knows at first what has happened; and when the nature of the case is afterwards manifested, by the discharge of blood per anum, an extravasation of intestinal matter, &c. it would be impossible to get at the injured part of the bowel, not only because its exact situation is unknown, but more particularly on account of the adhesions, which are always formed with surprising rapidity. But even if the surgeon knew to a certainty, in the first instance, that one of the bowels was wounded, and the precise situation of the injury, no future could be applied, without considerably enlarging the external wound, drawing the wounded intestine out of the cavity of the abdomen, and handling and disturbing all the adjacent viscera. Nothing would be more likely than such proceedings to render the accident, which might originally be curable, unavoidably fatal. We must agree upon this point with Mr. John Bell, who says, "When there is a wounded intestine, which we are warned of only by the passing out of the feces, we must not pretend to search for it, nor put in our finger, nor expect to sew it to the wound; but we may trust that the universal pressure, which prevents great effusion of blood, and collects the blood into one place, that very pressure, which always causes the wounded bowel and no other to protrude, will make the two wounds, the outward wound and the inward wound of the intestine, oppose each other point to point; and if all be kept there quiet, though but for one day, so lively is the tendency to inflame, that the adhesion will be begun, which is to save the patient's life." Discourses on Wounds, p. 361. edit. 3.

When the extravasation and other symptoms, a few days after the accident, evince the nature of the case, a future can be of no use whatever, as the adhesive inflammation has already fixed the part in its situation, and the space, in which the extravasation lies, is completely separated from the general cavity of the abdomen by the surrounding adhesions.

When the bowel is not protruded, and the opening in it is situated closely behind the wound in the peritoneum, a suture is not requisite; for the contents of the gut, not passing onward, will be discharged from the outer wound, and not be diffused among the viscera, if care be taken to keep the external wound open. There is no danger of the wounded bowel changing its situation, and becoming distant from the wound in the peritoneum; for the situation which it now occupies is its natural one. Nothing but violent motion, or exertions, could cause so unfavourable an occurrence, and these should always be avoided. The adhesions, which take place in the course of a day or two, at length render it impossible for the bowel to shift its situation. See Dict. of Pract. Surgery, edit. 3. art. *Wounds*.

In a penetrating wound of the abdomen, as a late author remarks, whether by gun-shot, or a cutting instrument, if no protrusion of intestine takes place, (and this, it must be observed, in musket or pistol wounds, rarely occurs,) the lancet, with its powerful concomitants, abstinence and rest, particularly in the supine posture, are our chief dependence. Great pain and tension, which usually accompany these wounds, must be relieved by leeches, if they can be procured, by the topical application of fomentations, and the warm bath; and if any internal medicine is given as a purgative, it must, for obvious reasons, be of the mildest nature. The removal of the ingesta, as a source of irritation, is best effected by frequently repeated oleaginous glysters; indeed, on the first infliction of a wound of the abdomen, the contents of the intestinal canal and stomach are generally evacuated spontaneously, the stools being sometimes tinged with blood. Their accumulation must be guarded against by a rigorous diet; for to the general state of fulness of the vessels induced by food, is added its local and mechanical stimulus in the undigested form. By this treatment, penetrating wounds, in which several plicæ of intestines have been necessarily implicated, have been happily cured. Authors abound with instances of this kind, and Mr. Hennen has seen several: among others, he was witness to the recovery of a soldier, who had been shot through the abdomen with a ramrod, at the siege of Badajos in 1812, which passed in anteriorly, and actually stuck in the vertebræ, from which it was not disengaged without the application of some force. Garengot and Lamotte also record cures, after the passage of swords completely through the body. See Hennen's Obs. on Military Surgery, p. 436, 437.

In all penetrating wounds of the belly, the dressings cannot be too simple and light.

In some instances, the ball, or part of the weapon which has inflicted the wound, remains within the abdominal cavity, and is afterwards evacuated by the natural passages.

Balls, says Mr. Hennen, frequently pass clean through the abdomen, evidently wounding the intestines, but without occasioning any protrusion of them at either of the orifices. These cases, like all others of those parts, are extremely dangerous, but are not necessarily mortal. They require the most guarded attention, and the utmost watchfulness of the approach of inflammation, which often comes on most insidiously. The mildest possible application should be employed to the wounds, and no plugging with tents

or introduction of medicated dressings thought of. (P. 440.) At first a common linseed poultice, and afterwards simple pledgets, are as eligible dressings as any which can be mentioned.

Extravasation in the Abdomen.—Wounds of the abdomen may be complicated with extravasations of blood, chyle, excrement, bile, or urine. None of these complications, however, are half so frequent as an unreflecting and inexperienced practitioner might apprehend. The employment of the phrase *cavity of the abdomen* has paved the way to much erroneous supposition upon this subject, and has induced many absurd notions, which even the sensible observations long ago published by Petit (le fils) have scarcely yet dispelled.

As a modern writer has observed, "there is not truly any cavity in the human body, but all the hollow bowels are filled with their contents, all the cavities filled with their hollow bowels, and the whole is equally and fairly pressed. Thus, in the abdomen all the viscera are moved by the diaphragm and the abdominal muscles, upwards and downwards, with an equable continual pressure, which has no interval; and one would be apt to add, the intestines have no repose, being kept thus in continual motion; but though the action of the diaphragm, and the re-action of the abdominal muscles, are alternate, the pressure is continual; the motion which it produces (they produce) is like that which the bowels have when we move forwards in walking, having a motion with respect to space, but none with regard to each other, or to the part of the belly which covers them; the whole mass of the bowels is alternately pressed, to use a coarse illustration, as if betwixt two broad boards, which keep each turn or intestine in its right place, while the whole mass is regularly moved. When the bowels are forced down by the diaphragm, the abdominal muscles recede: when the bowels are pushed back again, it is the re-action of the abdominal muscles that forces them back and follows them; there is never an instant of interruption of this pressure, never a moment in which the bowels do not press against the peritoneum; nor is there the smallest reason to doubt that the same points in each are continually opposed. We see that the intestines do not move, or at least do not need to move in performing their functions; for in hernia, where large turns of intestines are cut off by gangrene, the remaining part of the same intestines is closely fixed to the groin, and yet the bowels are easy, and their functions regular. We find the bowels regular when they lie out of the belly in hernia, as when a certain turn of intestine lies in the scrotum, or thigh, or in a hernia of the navel; and where yet they are so absolutely fixed, that the piece of intestine is marked by the straightness of the rings. We find a person, after a wound of the intestine, having free stools for many days; and what is it that prevents the feces from escaping, but merely this regular and universal pressure? We find a person on the fourth or fifth day with feces coming from the wound! a proof, surely, that the wound of the intestine is still opposite, or nearly opposite, to the external wound. We find the same patient recovering without one bad sign! What better proof than this could we desire, that none of the feces have exuded into the abdomen?"

"If in a wound of the stomach the food could get easily out by that wound, the stomach would unload itself that way, there would be no vomiting, the patient must die; but so regular and continual is this pressure, that the instant a man is wounded in the stomach he vomits, he continues vomiting for many days, while not one particle escapes into the cavity of the abdomen. The outward wound is commonly opposite to that of the stomach, and by that

passage some part of the food comes out; but when any accident removes the inward wound of the stomach from the outward wound, the abdominal muscles press upon the stomach, and follow it so closely, that if there be not a mere laceration extremely wide, this pressure closes the hole, keeps the food in, enables the patient to vomit, and not a particle, even of jellies or soups, is ever lost, or goes out into the cavity of the belly.

"How (proceeds Mr. J. Bell), without this universal and continual pressure, could the viscera be supported? Could its ligaments, as we call them, support the weight of the liver? Or, what could support the weight of the stomach when filled? Could the mesentery or omentum support the intestines; or could its own ligaments, as we still name them, support the womb? How, without this uniform pressure, could these viscera fail to give way and burst? How could the circulation of the abdomen go on? How could the liver and spleen, so turgid as they are with blood, fail to burst? Or, what possibly could support the loose veins and arteries of the abdomen, since many of them, e. g. the splenic vein, is (are) two feet in length, is (are) of the diameter of the thumb, and has (have) no other than the common pellucid and delicate coats of the veins? How could the viscera of the abdomen bear shocks and falls, if not supported by the universal pressure of surrounding parts? In short, the accident of hernia being forced out by any blow upon the belly, or by any sudden strain, explains to us how perfectly full the abdomen is, and how ill it is able to bear any pressure, even from its own muscles, without some point yielding, and some one of its bowels being thrown out. And the sickness and faintness, which immediately follow the drawing off of the waters of a dropsy, explain to us what are the consequences of such pressure being even for a moment relaxed. But perhaps one of the strongest proofs is this, that the principle must be acknowledged, in order to explain what happens daily in wounds; for though in theory we should be inclined to make this distinction, that the hernia, or abscess of the intestines, will adhere and be safe, but that wounded intestines, not having time to adhere, will become flaccid, as we see them do in dissections, and so, falling away from the external wound, will pour out their feces into the abdomen, and prove fatal; though we should settle this as a fair and good distinction in theory, we find that it will never answer in practice. Soldiers recover daily from the most desperate wounds; and the most likely reasons that we can assign for it are, the fulness of the abdomen, the universal, equable, and gentle pressure, and the active disposition of the peritoneum ready to inflame with the slightest touch. The wounded intestine is, by the universal pressure, kept close to the external wound, and the peritoneum and the intestine are equally inclined to adhere. In a few hours that adhesion is begun which is to save the patient's life, and the lips of the wounded intestine are glued to the lips of the external wound. Thus is the side of the intestine united to the inner surface of the abdomen; and though the gut casts out its feces while the wound is open, though it often casts them out more freely while the first inflammation lasts, yet the feces resume their regular course whenever the wound is disposed to close." John Bell's Discourses on Wounds, p. 323—327, edit. 3.

The foregoing extract, though drawn up in the most careless style, contains such observations as are well calculated to make the reader understand that the abdomen is in reality not a cavity, but a compact mass of containing and contained parts; that the close manner in which the various surfaces are constantly in contact must powerfully oppose extravasations; and that in fact it often entirely prevents them.

them. The passage cited impresses us with the utility of that quick propensity to the adhesive inflammation which prevails throughout every peritoneal surface, and which not only often has the effect of permanently hindering effusion of the contents of the viscera, by agglutinating the parts together, but which, even when an extravasation has happened, beneficially confines the effused fluid in one mass, and surrounds it with such adhesions of the parts to each other as are rapid in their formation, and effectual for the purposes of limiting the extent of the effusion, and preventing the irritation of the extravasated matter from affecting the rest of the abdomen.

It is to M. Petit that we are indebted for the introduction of more correct modes of thinking upon the foregoing subject. See *Mém. de l'Acad. de Chirurgie*.

But notwithstanding the influence of the reciprocal pressure of the containing and contained parts against each other, and the useful effect of the quickly arising adhesive inflammation in all penetrating wounds of the belly, complicated with the injuries of the viscera, we are not to suppose that extravasation never happens, but only that it is much less frequent than has been commonly supposed. Mr. Travers, with much laudable industry, has endeavoured to trace more minutely than any preceding writer the particular circumstances under which effusions in the abdomen are likely or unlikely to happen. "It being admitted (says he) that there are cases in which effusion does take place, it is easy to conceive circumstances which must considerably influence this event. If, for example, the stomach and bowels be in a state of emptiness, the nausea which follows the injury will maintain that state. If the extent of the wound be considerable, the matter will more readily pass through the wound than along the canal. A wound of the same dimensions in the small and the large intestines will more readily evacuate the former than the latter, because it bears a larger proportion to the calibre. Incised and punctured wounds admit of the adhesion of the cut edges, or the eversion of the internal coat of the gut, so as to be in many instances actually obliterated; whereas lacerated or ulcerated openings do not admit of these salutary processes. Again, in a transverse section of the bowel, contraction of the circular fibre closes the wound, whereas in a longitudinal section, the contraction of this fibre enlarges it. Such (says Mr. Travers) are the circumstances which, combined in a greater or less degree, increase or diminish the tendency to effusion." On *Injuries of Intestines*, &c. p. 13, 14.

After the details of some experiments and cases, the preceding author makes among other conclusions the following:

1. That effusion is not an ordinary consequence of penetrating wounds.
2. That if the gut be full, and the wound extensive, the surrounding pressure is overcome by the natural action of the bowel tending to the expulsion of its contents.
3. That if food has not recently been taken, and the wound amounts to a division of the gut, or nearly so, the eversion and contraction of the orifice of the tube prevent effusion.
4. That if the canal be empty at the time of the wound, no subsequent state of the bowel will cause effusion, because the supervening inflammation agglutinates the surrounding surfaces, and forms a circumscribed sac; nor can effusion take place from a bowel at the moment full, provided it retains a certain portion of its cylinder entire, the wound not amounting nearly to a semi-division of the tube, for then the

eversion and contraction are too partial to prevent an extravasation.

5. That when, however, air has escaped from the bowel, or blood has been extravasated in quantity within the abdomen at the time of the injury, the resistance opposed to effusion will be less effectual, although the parietal pressure is the same, as such fluids will yield more readily than the solids naturally in contact. P. 25, 26. 100.

6. That though extravasation is not common in penetrating wounds, it follows more generally in cases where the bowel is ruptured by blows, or falls upon the belly, while the integuments continue unwounded. P. 36.

7. That when the bowels are perforated by ulceration, there is more tendency to effusion than in cases of wounds. P. 38, &c.

Mr. Travers explains the reason of the greater tendency to effusion, in cases of intestines burst by violence, and in those of ulceration, "by the difference in the nature of the injury which the bowel sustains when perforated by a sword or bullet, as in the one case, or burst or ulcerated in the other. A rupture by concussion could only take place under a distended state of the bowel, a condition most favourable to effusion, and from the texture of the part, a rupture so produced would seldom be of limited extent. The process of ulceration, by which an aperture is formed, commences in the *internal* coat of the bowel, which has always incurred a more extensive lesion than the peritoneal covering. The puncture or cut is merely a solution of continuity in a point or line; the ulcerated wound is an actual loss of substance. The consequence of this difference is, that while the former, if small, is glued up by the effusion from the cut vessels, or, if large, is nearly obliterated by the full eversion of the villous coat, the latter is a permanent orifice." P. 46.

Blood is more frequently extravasated in the abdomen than any other fluid. Extravasations of this kind, however, do not invariably happen, whenever vessels of not a very considerable size are wounded. The compact state of the abdominal viscera, in regard to each other, and their action on each other, oppose this effect. The action alluded to, which depends on the abdominal muscles and diaphragm, is rendered very manifest by what happens in consequence of operations for herniæ attended with alteration of the intestines, or omentum. If these viscera should burst or suppurate after being reduced, the matter which escapes from them, or the pus which they secrete, is not lost in the abdomen, but is propelled towards the wound of the skin, and there makes its exit. The intestinal matter effused from a mortified bowel has been known to remain lodged the whole interval between one time of dressing the wound and another, in consequence of the surgeon stopping up the external wound with a large tent. When the above-mentioned action or pressure of the muscles is not sufficient to keep the blood from making its escape from the vessels, still it may hinder it from becoming diffused among the convolutions of the viscera, and thus the extravasation is confined in one mass. The blood, effused and accumulated in this way, is commonly lodged at the inferior and anterior part of the abdomen, above the lateral part of the pubes, and by the side of one of the recti muscles. The weight of the blood may propel it into this situation, or perhaps there may be less resistance in this direction than in another. In opening the bodies of persons who have died with such extravasations, things may put on a different aspect, and the blood seem to be promiscuously extravasated over every part of the abdomen. But when such bodies are examined with care, it will be found that

the blood does not insinuate itself among the viscera till the moment when the abdomen is opened, and the mass previously lies in a kind of pouch. This pouch is frequently circumscribed, and bounded by thick membranes, especially when the extravasation has been of some standing. Sabatier, *Médecine Opératoire*, tom. i. p. 28—30.

It is of the highest consequence to a practical surgeon to remember well that all the parts contained in the abdomen are closely in contact with each other, and with the inner surface of the peritoneum. This is one grand reason why extravasations are seldom so extensively diffused as one might imagine, but commonly lie in one mass, as Petit, Sabatier, and all the best moderns, have noticed. The pressure of the elastic bowels, of the diaphragm, and abdominal muscles, not only frequently presents an obstacle to the diffusion of extravasated matter, but often serves to propel it towards the mouth of the wound. The records of surgery make mention of numerous instances in which persons have been stabbed through the body without any fatal consequences, and sometimes without the symptoms being even severe. In Mr. Travers's publication many cases exemplifying this observation are quoted from a variety of sources. Fab. Hildan. *Obs. Chirurg.* cent. v. obs. 74. *Œuvres de Paré*, liv. x. chap. 35. *Wife's Surgery*, p. 371. *La Motte's Traité Complet de Chirurgie*, &c. &c. In such cases, the bowels have been supposed to have eluded the point of the weapon, and this may, perhaps in a few instances, have been actually the fact; but in almost all such examples there can be no doubt that the bowels have been punctured, and an extravasation of intestinal matter has been prevented by the opposite pressure of the adjacent viscera. Such resistance and pressure may also have occasionally obliged intestinal matter, or blood actually extravasated, to pass through the wound of the bowel into its cavity, and thus be speedily removed. Certain it is, such copious evacuations of blood *per anum* have followed stabs of the abdomen as could hardly proceed from the arteries of the intestines. This way of getting rid of an extravasation must be rare, however, compared with that by absorption.

The pouch or cyst including extravasated blood or matter, as mentioned by Sabatier, is formed by the same process which circumscribes the matter of abscesses. (See SUPPURATION.) It is in short the adhesive inflammation. All these surfaces in contact with each other, and surrounding the extravasation and track of the wound, generally soon become so intimately connected together by the adhesive inflammation, that the place in which the extravasation is lodged is a cavity entirely destitute of all communication with the cavity of the peritoneum. The track of the wound leads to the seat of the effused fluid, but has no distinct opening into the general cavity of the abdomen. The rapidity with which the above adhesions form is often very great, almost incredible.

Urine and bile are more frequently dispersed to a great extent among the abdominal viscera than blood. The latter fluid, indeed, must often coagulate; a circumstance that must both tend to stop further hemorrhage, and confine the extravasation in one mass.

Symptoms and Treatment of Extravasations in the Abdomen.

—1. *Blood.*—Wounds of the spleen, and of such veins and arteries as are above a certain size, almost always prove fatal from internal hemorrhage. The blood generally makes its way downwards, and accumulates at the inferior part of the abdomen, unless the existence of adhesions happen to oppose the descent of the fluid to the most depending situation. The belly swells, and the fluctuation of a fluid is per-

ceptible through the anterior part of the abdominal parietes. The patient grows pale, loses his strength, is affected with syncope, and his pulse becomes weaker and weaker. In short, the symptoms usually attendant on hemorrhage are observable. The viscera and vessels in the abdomen being continually compressed on all sides by the surrounding parts, the blood cannot be effused without overcoming a certain degree of resistance; and unless a vessel of the first magnitude, like the aorta, the vena cava, or one of their principal branches, has been wounded, the blood escapes from the vessel slowly, and several days elapse before any considerable quantity has accumulated in the lesser cavity of the pelvis.

In these cases of extravasated blood, the symptoms, which perhaps had disappeared under the employment of bleeding and anodyne medicines, now come on again. A soft fluctuating tumour may be felt at the lower part of the abdomen, sometimes on the right side, sometimes on the left, occasionally on both sides. The pressure made by the effused blood on the urinary bladder excites distressing inclinations to make water; while the pressure which the sigmoid flexure of the colon suffers is the cause of obstinate constipation. In the mean time, the quantity of extravasated blood increasing, irritation and inflammation of the peritoneum are induced. The pulse grows weaker, debility ensues, the countenance is moistened with cold perspirations; and, unless mitigated by all the antecedent circumstances, the surgeon practises an incision for the discharge of the fluid, the patient falls a victim to the accident.

In the year 1733, Vacher, principal surgeon of the military hospital at Besançon, successfully adopted this mode of treatment. Petit (the son) afterwards tried the same plan, though it did not answer, (as is alleged,) in consequence of the inflammation having advanced too far before the operation was performed. Long before the time of Vacher and Petit, a successful instance of similar practice had been recorded by Cabrol.

Indeed, when the symptoms leave no doubt of there being a large quantity of blood extravasated in the abdomen; when the patient's complaints are of a very serious nature, and are evidently owing to the irritation and pressure of the blood on the surrounding viscera; and when a local swelling denotes the seat of the extravasation, there cannot be two opinions about the propriety of making an incision for its evacuation.

Surgeons, however, should recollect, that a small extravasation of blood may exist without producing any considerable irritation, provided no opening be made into the cyst with which it becomes surrounded. On the contrary, when such cyst is opened, the air then having free access to the blood contained there, that part of the fluid which cannot be discharged is apt to putrefy, and become so irritating, as to excite inflammation of the surrounding parts.—Even though there may be an evident extravasation of blood, the bad symptoms are also sometimes entirely owing to the injury done to the parts within the abdomen, and neither to the pressure nor the irritation of the effused blood.

But sometimes, as we have already noticed, the accumulated blood at first neither irritates the adjacent parts by its quantity nor quality. An inflammation, however, of the parts surrounding the extravasation at length takes place. The tension, irritation, and pain, which in the first instance arose from the wound itself, and subsided, seem now to be renewed. When the extravasation is at the lower and anterior part of the abdomen, the patient experiences pain about the hypogastric region. He is also constipated, and as he suffers

suffers great irritation of the bladder, he feels frequent propensities to make water, but cannot relieve himself. At last a tumour makes its appearance, attended with a fluctuation more or less distinct.

In this instance, it seems proper to give vent to the accumulated blood. If this fluid should be found coagulated, injections of warm water would facilitate its discharge. Sabatier, *Médecine Opératoire*, tom. i.

2. *Chyle and Feces*.—These are not so easily extravasated in the abdomen as blood, because they do not require so much resistance on the outside of the stomach and intestines, to make them continue their natural route through the alimentary canal, as blood requires to keep it in the vessels. Extravasations of this kind, however, sometimes happen when the wound is large and the bowel distended at the moment of the injury, or when, as Mr. Travers has likewise explained, air is extravasated, or blood effused in the abdomen; these fluids being incapable of making effectual resistance to the escape of the intestinal matter. (See an Inquiry into the Process of Nature in repairing Injuries of the Intestines, &c. p. 26.) Nothing is a better proof of the difficulty with which chyle and feces are extravasated than the operation of an emetic, when the stomach is wounded and full of aliment. In this instance, if the resistance to the extravasation of the contents of the stomach were not considerable, they would be effused in the abdomen, instead of being vomited up. A peculiarity in wounds of the stomach and intestines is, that the opening which allows their contents to escape may also allow them to return into the wounded viscus.

Extravasation of intestinal matter in the abdomen is attended with a severe train of febrile symptoms; dryness of the mouth, tongue, and fauces; considerable pain and swelling of the belly; convulsive startings; and hiccough and vomiting, with which the patients are generally attacked on the day after that on which the wound was received. Sabatier de la *Médecine Opératoire*, tom. i. p. 34.

In these cases, general means are the only ones which can be employed; venesection, fomentations, low diet, perfect rest, anodynes, &c. All solid food must be most strictly prohibited. The close state of the viscera may also be increased by applying a bandage round the body.

If the symptoms are not speedily alluaged, the abdominal viscera become affected with general inflammation and gangrene, and the patients die in the course of a few days.

3. *Bile*.—Bile, on account of its great fluidity, is more easily extravasated extensively in the abdomen than either blood or the contents of the stomach and intestines. Besides, the gall-bladder has the power of contracting itself so completely as to expel the whole of its contents. Notwithstanding these circumstances, however, extravasations of this kind are exceedingly uncommon, doubtless on account of the small size of the gall-bladder, and its deep-guarded situation, between the concave surface of the liver and upper part of the transverse arch of the colon.

Sabatier informs us, that he has only been able to find one example on record. This case, after having been communicated to the Royal Society of London by Dr. Steward (N^o 414, p. 341. Abridgm. tom. vii. p. 571, 572.), was inserted as an extract in the third volume of the *Edinburgh Essays*, and also in the third volume of Van Swieten's *Commentaries on the Aphorisms of Boerhaave*. (Transl. p. 65. edit. 1754.) An officer received a wound, penetrating the cavity of the abdomen, and entering the fundus of the gall-bladder, without doing any material injury to the adjacent parts. The abdomen was immediately distended, as if the patient had been afflicted with an ascites, or tympanitis;

nor did the swelling either increase or diminish till the patient's death, which happened a week after the infliction of the wound.

There was no rumbling noise in the abdomen, though it was exceedingly tense. There were no stools, and very little urine was discharged, notwithstanding purgatives and glysters, and a good deal of liquid nourishment, were given. The patient never had one instant of sound sleep, but was always restless, though anodynes were exhibited. There was no appearance of fever, and the pulse was always natural till the last day of the patient's life, when it became intermittent. The intestines were found, after death, very much distended, the gall-bladder quite empty, and a large quantity of bile extravasated in the abdomen.

Sabatier met with an opportunity of observing the symptoms of an extravasation of bile, in consequence of a wound of the gall-bladder. The patient's abdomen swelled very quickly; his respiration became difficult, and he soon afterwards complained of tension, and pain in the right hypochondrium. His pulse was small, frequent, and contracted; his extremities were cold, and his countenance very pale. The bleedings which were practised the first day gave him a little relief; but the tension of the abdomen, and the difficulty of breathing, still continued. A third bleeding threw the patient into the lowest state of weakness, and he vomited up a greenish matter. On the third day, the lower part of the belly was observed to be more prominent, and there was no doubt of an extravasation. M. Sabatier introduced a trocar, and gave vent to a green blackish fluid, which had no smell, and was pure bile, that had escaped from the wound of the gall-bladder. After the operation, the patient grew weaker and weaker, and died in a few hours. On opening the body, a large quantity of yellow bile was found between the peritoneum and intestines; but it had not insinuated itself among the convolutions of the viscera. A thick gluten connected the bowels together, and they were prodigiously distended. The gall-bladder was shrivelled, and almost empty. Towards its fundus, there was a wound about a line and a half long, corresponding to a similar wound in the peritoneum. The wound which had occurred at the middle and lower part of the right hypochondrium, between the third and fourth false ribs, had glided from behind forward, and from above downward, between the cartilages of the ribs, until it reached the fundus of the gall-bladder.

Sabatier takes notice, that the symptoms of the two cases which have just now been related were very similar. Both the patients were affected with an exceedingly tense swelling of the belly, unattended with pain or borborygmus, and they were both obstinately constipated. Their pulse was extremely weak the latter days of their indisposition, and they were afflicted with hiccough, nausea, and vomiting.

M. Sabatier seems to think one thing certain, *viz.* that wounds of the gall-bladder, attended with effusion of bile, are absolutely mortal, and that no operation can be of any avail. *Médecine Opératoire*, tom. i. p. 34—37.

We are, however, to infer the contrary from the extraordinary case lately published by Mr. Fryer of Stamford. A boy, about thirteen years old, received a violent blow from one of the shafts of a cart, on the region of the liver. The injury was succeeded by pain, frequent vomiting of bilious matter, great sinking, coldness of the extremities, and a weak, small, fluttering pulse. The belly was fomented, and purging clysters thrown up. On the third day, symptoms of inflammation began, attended with considerable pain about the liver, great tension and foreness of
the

the abdomen, and frequent vomiting. The pulse was quick, small, and weak, the skin hot and dry, the tongue much furred, the urine high coloured; and there was some difficulty of breathing, and great thirst. Eight ounces of blood were taken away, the fomentations continued, and a few grains of calomel were directed to be given every four hours, until the bowels were properly opened. Afterwards the effervescing mixture, with ten drops of laudanum, was exhibited every four hours.

On the following day, the patient had had some motions, and was much better; but as his sickness continued, he was ordered a grain of opium every four hours. About a week afterwards, he complained of a great increase of pain, which was somewhat relieved by a blister. He was now completely jaundiced, and his stools were white, but the tension, pain, and sickness, were abated.

Two days afterwards, a fluctuation was perceived in the abdomen, which in another week became considerably distended with fluid. The patient now did not complain of much pain, but appeared to be sinking fast; a puncture was made in the swelling, and thirteen pints of what appeared to be pure bile were evacuated. The bowels then soon became regular, and the appetite good. In twelve days, the operation was repeated, and fifteen pints of the same bilious fluid were drawn off. Nine days afterwards, another puncture was made, and thirteen pints more let out; and six were discharged in another fortnight. From this period the boy went on well, and perfectly recovered under the use of light tonic medicines. See *Medico-Chirurgical Transactions*, vol. iv. p. 330.

A previous accidental adhesion of the gall-bladder to the peritoneum might also certainly prevent the extravasation of bile, and its dangerous effects. Callisen, *Syst. Chir. Hoediernæ*, tom. i. p. 718.

Mr. Hennen has never known a patient recover after a wound of the gall-bladder; and indeed, says he, it is difficult to imagine a case where the injury could happen without an effusion of bile into the abdominal cavity, except a previous adhesion had taken place to the parietes. A case, however, is mentioned in the "*Opusculæ de Chir.*" of M. Paroisse, where a leaden ball had lodged in the gall-bladder two years.

4. *Urine*.—Urine being of a very fluid nature may, like the bile, be easily extravasated in the abdomen, when the bladder is wounded at any part which is connected with the peritoneum. If the urine in this kind of case be not drawn off with a catheter, so as to prevent it from issuing by the wound of the bladder, the patient soon perishes. There are many instances recorded of the bladder being injured even by gun-shot wounds which were not mortal. (See Larrey's *Mém. de Chir. Mil.* especially tom. iv.) Such wounds, however, might only have injured the sides or lower part of the bladder. But in operating for the stone above the pubes, the bladder has undoubtedly been occasionally cut at the part of the fundus which is covered with the peritoneum. However, as the accident was known in the first instance, the right treatment was adopted, and such patients have recovered. Sabatier, *Médecine Opératoire*, tom. i. p. 37.

Wounds of the bladder are particularly characterized by a discharge of bloody urine and difficulty of making water. They must always be regarded as dangerous cases, both on account of the risk of the effusion of so irritating a fluid in the abdomen, and of the chance of extravasation in the cellular membrane. Under proper treatment, however, they often admit of cure. The effused fluid should, if possible, be discharged by a depending posture, or suitable punctures or incisions, and its recurrence prevented by the introduction

of a catheter, which is to be left in the urethra. The patient must also be allowed little drink. As for the tension and pain of the belly, the perpetual attendants of a wounded bladder, they may be greatly relieved by the use of the warm bath. (Callisen, tom. i. p. 719.) Bleeding and other antiphlogistic means are not to be omitted. See *Dict. of Pract. Surg.* art. *Wounds*.

Extraneous bodies, particularly balls, as Mr. Hennen observes, are frequently carried into the bladder itself, either as it rises above the pubes or through the openings in the pelvis, or work their way into it, and either come off by the natural passage, or are removed by a surgical operation resembling lithotomy. Wounds of the bladder, he remarks, are dangerous in proportion as it is full of urine at the time of their receipt, or as the upper and anterior, or lower and posterior part of the viscus may be wounded. If the intestines are implicated in the wound, it is highly dangerous. Inflammation from wounds of these parts runs rapidly into gangrene, which is chiefly brought on by the effusion of urine in the cellular membrane. "If there is a free extensive passage, much of this danger will be obviated; and after the first effusion from the bladder has taken place, the judicious use of the elastic gum catheter affords us an admirable assistance against this accident." "Indeed," says Mr. Hennen, "without this useful instrument, our practice in wounds of this nature, and in those affecting the urethra, would be merely confined to looking on and moderating symptoms, instead of preventing them." (P. 460.) The rest of the treatment consists in letting out, without delay, the effused urine by proper incisions, and employing the antiphlogistic plan, in the full sense of the expression, together with mild superficial dressings or poultices, and the utmost attention to cleanliness.

A deep wound of the liver, Mr. Hennen considers as fatal as one of the heart itself. Slighter injuries of this organ, he sets down as sometimes recovering. He says, that the usual symptoms which characterize wounds of the liver are, yellowness of the skin and urine, derangement of the stomach and of the alimentary canal, and cutaneous affections, particularly great and distressing itching. The discharge from the wound is generally yellow and glutinous; but he has seen it of a ferous nature, and sometimes very nearly allied to unmixed bile.

Wounds of the liver, says another writer, may cause a large effusion of blood from the outer wound, or in the abdomen, a cadaverous yellow countenance, pain in the shoulder, slow pulse, dulness of the eyes, great anxiety, cold sweats, and finally death, which happens the more quickly and certainly, the greater the wound is, and the nearer it is situated to the place where the large vessels enter this organ. But small wounds of the liver, particularly of its convex surface, when it is adherent to the peritoneum, admit of cure. Callisen, tom. i. p. 718.

The treatment is to be at first conducted entirely on antiphlogistic principles, venesection, and mild aperient medicines in particular being employed. Afterwards small doses of the pil. hydrarg. and tonic medicines will tend to re-establish the health.

A wound of the stomach may be known by the discharge of aliment from the external opening; by the vomiting of blood; the pain, the anxiety, and other symptoms of violent nervous irritation. Large wounds of this organ, especially those about the cardiac orifice, or great curvature, or such as extend through both sides of the viscus, are for the most part fatal in a few days: but when the wound is differently situated, and properly treated, it may often be cured. In certain instances, however, a fistula remains, through which

a part of the food sometimes escapes. Two cases of wounds of the stomach are recorded by Dr. Thomson, in his *Obs. on the Military Hospitals in Belgium*. One was from a musket-ball; the other from a pike. They were treated on the mild, unirritating plan, adapted for wounds of the intestines, and both ended well. "The histories of the Bohemian, Prussian, and English 'cultrivores,' from some of whom the knives have been cut out, and from others discharged spontaneously, through the coats of the stomach and parietes of the abdomen; as well as many other instances on record, are (as Mr. Hennen observes) very encouraging in cases of injuries of this organ." M. Hevin, in the *Mém. de l'Acad. de Chir. tom. i. p. 144.* has collected a number of interesting instances of recovery, both from incised and gun-shot wounds. But (says Mr. Hennen) the industrious Plouquet, in the articles "Ventriculus" and "Pantophagi," has exceeded all others for the vast number of cases he has amassed. In our own *Philosophical Transf., Lowthorpe's Abridgment, vol. vi. p. 192.* or in the modern one, by Drs. Hutton, Shaw, and Pearson, *vol. iv. p. 66.* an instance is given, where the stomach of a horse was wounded and sewed up, and a similar instance in the human species: both recovered. More recently sutures have been applied to its wounds in Holland and France, as may be seen in the "*Annales de Litterature,*" &c. by Kluyfskens, *vol. 2.* and in the "*Traumalogia*" of Schlichting, &c. Notwithstanding these narratives, however, we have no doubt of the rashness of such practice, and all that can be said about it is, that the patients had to overcome both the injury and the bad treatment of it. Not unfrequently a wound of the stomach has become fistulous. Richerand gives a very curious case of this kind, where the opening remained for nine years; Etmuller, in the 5th vol. of Haller's "*Disputationes Chirurgicæ,*" gives an instance, where it continued open for ten years; and Wenker, in the same volume, relates a case where a wound of the stomach continued open twenty-seven years. (See Hennen on Military Surgery, p. 481, &c.) Copious bleeding, abstinence, and rest, are the best remedies in the early stage of all such cases.

Wounds of the spleen mostly prove fatal by the profuse hemorrhage arising from them. Mr. Hennen, however, assures us, that he has seen some slight wounds of this viscus terminate favourably. It has sometimes been cut out of brutes, without any fatal or even any bad consequences; and there is a recent instance recorded, in which it protruded from an incised wound, the surgeon removed it, and the patient got well. (See *Medico-Chirurg. Journal, vol. i. 1816.*) It has also been tied and cut out in some other instances with success. See cases in Gooch's *Chir. Works, vol. i. p. 97;* Leveillé's *Doctr. Chir. tom. i. p. 400;* also some references in Thomæ Bartholini *Anatome, p. 158. 8vo. Lugd. Bat. 1686, &c.*

Wounds of the spleen have scarcely any symptom which is peculiar to them. According to Celsus, however, there is great pain in the shoulder, as in wounds of the liver. The loose structure of the spleen, and the magnitude of its vessels, must always render its injuries highly dangerous.

Wounds of the pancreas, according to Callisen, are not characterized by any peculiar symptom, except the effusion of a fluid analogous to the saliva. The pancreas, like the duodenum, can hardly be wounded, without the weapon having at the same time injured other viscera. (*Syst. Chir. Hodiernæ, tom. i. p. 719.*) Gooch sets down wounds of the pancreas as mortal, if its duct or blood-vessels be injured. *Chir. Works, vol. i. p. 99.*

Wounds of the kidneys and ureters are always dangerous, on account of the hemorrhage and effusion of urine. When

the latter fluid insinuates itself within the peritoneum, or into the cellular membrane, the patient has but a very discouraging chance of preservation. Small wounds of the kidney, however, may be cured, though a fistula will sometimes remain. The danger of wounds of the kidney is well pointed out in M. Hevin's *Essay on Nephrotomy, in the Mém. de l'Acad. de Chir.,* and a great mass of evidence is produced on the subject. The recoveries which Mr. Hennen has seen, after wounds of the kidneys, he observes, are very few indeed. "If the patient has survived the first hemorrhage, the fever and peritoneal inflammation, with incessant hiccough and vomiting from sympathy of the diaphragm and stomach, have generally cut him off; and if he has for a time escaped, excruciating pains, profuse suppuration from fistulous fores, hectic, and emaciation, have terminated his existence. Where the cure has been effected, there is reason to think that the ureter has been but slightly brushed, and the body of the kidney itself left untouched. The remedies consist in venesection, mild purgatives, as manna, oil, &c. frequent emollient enemata, the warm bath generally, and local fomentations, &c. with a diet of the mildest kind, but much restricted in fluids, the indulgence in which, even in small quantity, should be avoided." The same author properly condemns all stimulants, blisters, and diuretics; and he recommends light dressings, so as to allow the urine to escape freely. The integuments near the wound he also advises to be greased, so as to prevent the irritation of the urine from making them inflame and ulcerate. See *Obs. on Military Surgery, p. 454.*

The subject of wounds is one of infinite length, and this must apologize for the extent of the present article, in which a great deal is still omitted. Had we introduced a full account of the wounds of every part of the body, our observations would have formed a production more than twice as long as that which we have now finished; but we thought that so minute and elaborate a paper would hardly be desirable in a work not expressly allotted to the consideration of surgery.

WOUNDS in Horses. The most terrible wounds these creatures are subject to are those got in the field of battle. The farriers that attend camps have a coarse way of curing these; but it is a very expeditious and effectual one. If the bullet be within reach, they take it out with a pair of forceps; but if it lie too deep to be come at, they leave it behind, and dress up the wound in the same manner as if it were not there.

They first drop in some varnish from the end of a feather, and when the bottom is thus wetted with it, they dip a pledget of tow in the same varnish, which they put into the wound, and then cover the whole with the following charge: Take a quarter of a pound of powder of bole armenic, half a pound of linseed-oil, and three eggs, shells and all; add to these four ounces of bean-flour, a quart of vinegar, and five ounces of turpentine; this is all to be mixed over the fire, and the wound covered with it. This application is to be continued four or five days, then the tent put into the wound is to be dipped in a mixture of turpentine and hog's-lard; by this means a laudable matter will be discharged, instead of the thin sharp water that was at first. Then the cure is to be completed by dressing it with an ointment made of turpentine, first well washed, and then dissolved in yolks of eggs, and a little saffron added to it.

This is the practice in deep wounds that do not go through the part; but in cases where the bullet has gone quite through, they take a few weavers' linen thrumbs, made very knotty; these they make up into a kind of link, and dipping it in varnish, they draw it through the wound,

leaving the ends hanging out at each side; by means of these they move the link or skein three or four times a day, always wetting the new part that is to be drawn into the wound with fresh varnish. They put on a charge of the bole armenic, &c. as before described, on each side of the wounded part, and continue this as long as the wound discharges thin watery matter, or the sides continue swelled. After this they dress it with the ointment of the turpentine, yolks of eggs, and saffron, till it is perfectly cured.

The other methods are, the dressing of the wound with an ointment made of wax, turpentine, and lard, and covering it with linen rags wetted with cream; or the dressing with a mixture of yolks of eggs, honey, and saffron, and covering it up with cream and baum-leaves beaten together.

When the wound is so dangerous as to require the assistance of internal medicines, they give the following pills: Take assafœtida, bay-berries, and native cinnabar, of each a pound; beat up the whole into a mass with brandy, and roll it into pills of fourteen drachms each. These are to be laid in a shady place to dry, after which they will keep ever so long without any damage. The horse is to take two of these every other day, or, if necessary, every day, till he has taken eight or ten of them, and he is to stand bridled two hours before and after the taking of them.

When the wound seems at a stand, not appearing foul, and yet not gathering new flesh, there must be recourse had to the following powder, whose effect in bringing new flesh is wonderful: Take dragon's blood, and bole armenic, of each two ounces; mastic olibanum, and sarcocolla, of each three drachms; aloes, round birth-wort, and common iris-root, of each one drachm and a half; make the whole into a fine powder. This is sometimes used dry, sprinkling it on the wound; but sometimes it is mixed with turpentine, sometimes with juice of wormwood, and sometimes with honey of roses, and either way does very well.

When the wound grows foul, and requires a detergent to cleanse it, the common liquor for this purpose is a plagedenic water, which they make of lime-water, and sublimate in this manner: Take two pounds and a half of newly-made and unslaked lime, put it into a pewter vessel, and pour on it five quarts of boiling water. When the bubbling is over, let it stand to rest two or three days, stirring it often with a stick; then pour it clear off after due time for the lime to settle, and filtre it through some whited-brown paper, made for the lining of funnels, on this occasion. To a quart of the clear lime-water, thus prepared, add eight ounces of spirit of wine, and one ounce of spirit of vitriol; when these are well mixed, by shaking them together, then add an ounce of corrosive sublimate in fine powder: mix all well together, and keep the whole in a bottle, to be used for the cleansing of these foul wounds, and on any other occasions, where a detergent of this powerful kind may be necessary. It will keep good many years.

If this water will not thoroughly cleanse the wound, but there still will remain a quantity of foul matter in it, and there is danger of a gangrene, they add to it as much arsenic in fine powder as there was of the corrosive sublimate; that is, at the rate of an ounce to a quart and half a pint.

These are all the medicines which the farrier need carry with him on account of wounds; and they are all such as may be prepared at home, and will continue good so long as he has occasion to keep them, or much longer; and what is left of one year will serve for others.

When the necessary applications are thus settled, it may not be improper to add the general rules by which they conduct themselves in the cure.

1. The wound must be probed at first, but very gently,

and afterwards as gently and as seldom as may be, for the horse's flesh is the most easy of all others to be contused in wounded parts, and to fall into a gangrene from the hurt. 2. The wound must be kept continually as clean as possible, and free from proud flesh. 3. The necessary revulsion must always be made by bleeding, as soon as the wound is dressed the first time; this prevents inflammation, and a great many other bad accidents. 4. If the wound be in such a place that the horse can get at it with its tongue to lick it, great care must be taken to prevent his doing so, as it will greatly retard the cure. 5. The farrier never is to proceed to suppuration in any case in which the humours can be either dissolved or repelled, and especially in parts that are full of sinews and ligaments, or that are near the bones. 6. If a wound be accompanied with a great contusion, or if it be of a round or circular figure, incisions are often necessary about its edges, and sometimes the application of caustics. 7. The wound must be always carefully covered, for the access of the air retards the cure. 8. The callous lips of a wound must always be cut to the quick, before they can be united together. These may serve for general rules, that hold good in all cases: and to these may be added some that are principally applicable to peculiar circumstances of the wounds.

Wounds of the breast are to be cured with tents and folds of soft linen laid over them, steeped in the following mixture: Take verdigrise, vitriol, and alum, of each one ounce; vinegar, eight ounces; honey, a pound; let all these be boiled together till they become red.

Wounds in the belly can only be cured by sewing up the peritoneum with strong woollen thread, not silk, leaving the extremities without the skin. The skin is to be sewed together with strong hempen thread waxed, joining the lips of the wound together, by this means, in form of a buckle. This is to be covered with the common ointment for wounds; and if an inflammation comes on, chalk dissolved in vinegar is to be added.

If the wound be such that the guts come out at it, the horse may still be recovered, if proper caution be used: the guts are to be immediately returned into their place; but they must not in this be touched with the hand, but with a sponge dipped in warm water. And, in order to the making them more readily get into their places, it is proper to make the creature vomit, by thrusting down his throat a feather dipped in oil. If the wound through which they fell is not big enough to return them easily by, it must be enlarged by cutting; but if the guts are found to be bruised or wounded, it is in vain to attempt any thing, for death must follow.

There is also a certainty of death when, after a wound of any kind in the belly, the horse voids blood at the fundament.

When a horse is wounded near the groin, he easily falls into convulsions; in this case, he is to be kept from drinking as much as possible: he is also to be covered well up, and kept quiet, and to have green things given him to eat.

Wounds on the knees are very difficult to cure, because the part is in motion almost continually, and there is very little flesh to work upon. When the wounds are but slight, and in the muscular parts of the body, a mixture of honey and tallow, boiled together, will often prove a cure; when the wound is more considerable, turpentine melted in a little common oil, and applied hot, is the general remedy.

If a wound happens between the shoe and the hoof, care must be taken that no foreign matter be left in it, and it must be dressed with any of the ointments that have verdigrise in them; and a charge of bruised elder-leaves is very proper

proper to be applied over all. If the wound be deep and narrow, it must be enlarged at the orifice, and turpentine and wax, melted in lard, must be poured into it. The same rule of opening the orifice holds good in all deep and narrow wounds.

If a nerve happens to be cut, it must be closed, and a defenative must be applied, to prevent a concourse of humours to the part; a fomentation made of oil, wine, and honey, mixed together, is also very proper, wherever a nerve is hurt, and a poultice may be applied over all, made of marshmallow-roots boiled soft, with bread and milk.

If the horse happens to be wounded by a piece of wood, bone, or any other hard substance, part of which remains in the wound, this must be carefully taken out, whatever pain it may cost the creature to do it, and the wound must then be dressed with the common wound-ointments. In this, or any other case of a fresh wound, the washing it with oil of turpentine is an excellent method of preventing ill consequences.

WOUNDS in Trees, such as are caused in lopping and pruning their branches, or otherwise. Mr. Nichol, in his "Practical Planter," has shewn, that lopping of strong branches becomes not necessary, and that all wounding in pruning should be performed on or towards the extremities of boughs which have inferior laterals to partake of and divert their luxuriance of growth from injuring the stem or leader. It is also shewn, that from this mode little ill is to be apprehended, and consequently that the treatment of such wounds is simple, and which is so much the better for the plant and the interest of its owner. Such wounds require no other attention than being lopped clean off with a sharp knife or bill; and, if the saw is used, being afterwards smoothed with the knife. And it were to be wished, for the sake of much timber, which otherwise might have been rendered more valuable, that wounds of another description had been unnecessary, or had never been inflicted. The writer here alludes to the necessity of lopping by the bole all stumps, &c. occasioned by formerly-injudicious pruning, and the wanton folly of those who lop large branches by or near to the stem, when simply shortening them at a proper distance would answer a better purpose. But since it becomes necessary to clear formerly-injured trees of stumps, &c. in order to prevent farther decay, it also becomes a duty to follow the most rational and simple mode of treatment. With this view, it is briefly observed, that whenever it becomes necessary to lop a stump by the bole, or to shorten any branch larger than the wrist or ankle; in the former case, the wound should be to the quick, that is, to the level of the bark, on the stem at least; and in the latter, *obliquely* across the branch, so as, from its position, to prevent moisture from lodging: being careful to prevent laceration, by notching the bark underneath, before the amputated part falls down, or to one side. In both cases, the face of the wound and edges of the bark are to be made perfectly smooth with the knife; and in a few hours after, or so soon as they are quite dry, let the wound be carefully plastered with tar, (such as is used for sheep-smearing,) or laid over with white or blue lead, which has been well mixed up with oil, and rendered rather thicker than is commonly used for painting. The tar is, however, certainly preferable, being of a more healing nature; and if laid on in a thin state, it is not so apt to scale off by the action of the weather as the paint. This operation should be performed in the *fall* of the year; at which time, the wound is not so apt to crack, and likewise dries sooner than at any other season. If, however, in the course of the

ensuing summer, or at any subsequent period, the tar or paint is found to rend or scale off, care must be taken to renew and keep the platter sound and smooth, until the bark grow over and cover the wound; and this should be more particularly observed in respect of wounds on the trunk.

In the case of *polling* a tree, lopping an upright branch, or in training for ship-timber, stopping the leader, &c. when, from the upright position of the wounded part in question, plastering or painting, as above, might be deemed insufficient to prevent water from penetrating, and of consequence injuring the wood at the part affected; yet by this treatment, infection, or the farther decay of the rest of the tree, will be prevented. But there are some who ridicule the idea of using plaster of any kind, urging for argument that the bark grows as fast together of itself without this aid, and why bury in the heart of the tree a load of rubbish? But they certainly have not considered, that a decayed part of the vegetable being buried in its heart, cannot possibly again be renovated, or become sound timber; but, on the contrary, must operate to the corruption of the rest. And this question, why bury in the tree a load of rubbish? leads, it is said, to a decision in favour of using tar, since, besides that the body inclosed is quite thin, it is of a genial, healing nature, acts as a cement to the fracture, and afterwards becomes equally sound as the wood.

And this may be demonstrated by examining fir-trees which have been wantonly hacked *deeply*, had holes bored into them for fastening gates to, which have afterwards been removed, and above all in the operation of extracting rosin; in all which cases, the wound is closed up by the resinous juice of the tree, and generally becomes perfectly sound as the rest of the wood, although a blemish may be the consequence. Wherefore, with respect to resinous trees, nature prevents the necessity of our interference in the cure of wounds, other than the fracture of limbs; which it is certainly our duty to amputate, in order to prevent farther decay and unsightly appearance; but she will hastily cover the wound with the plaster superior to any we can prepare.

WOUND-Wort, in *Botany*, the name given to several figures belonging to different genera.

WOUND-Wort of Achilles. See **ACHILLEA**.

WOUND-Wort, Clown's, a species of *Stachys*. See **STACHYS**.

WOUND-Wort, Hercules's, or *All-heal*, the *laserpitium chironium* of Linnæus. This is a native of the warmer climates, and bears the colds of our own. Both the seeds and roots of this species are considerably warmer than those of the *garden* and *wild* parsnep. The roots and stalks have a strong smell and taste, resembling those of opoponax: and Boerhaave relates, that on wounding the plant in summer, he obtained a yellow juice, which, being inspissated a little in the sun, agreed perfectly, in both respects, with that exotic gum-resin. Lewis. See **LASERPITUM**.

WOUND-Wort, Saracen's, Solidago. See **SOLIDAGO**.

WOUND-Wort, True Saracen's, a species of *Senecio*. See **SENECIO**.

WOUNICS, in *Geography*, a town of Austrian Poland; 32 miles E.S.E. of Cracow.

WOUTERS, FRANCIS, in *Biography*, was born at Liere, in Brabant, in 1614. He was a student in the school of Rubens, but applied himself principally to landscape, and became one of the most eminent of his time. He chose for his models the scenes of his native country, and particularly the forest of Soignes, near Brussels; embellishing the views he chose with groups of figures representing historical or allegorical

allegorical subjects. Sometimes he attempted history, but not successfully. He was in favour with the emperor Ferdinand II.; but coming to England with his ambassador in 1637, he was appointed chief painter to the prince of Wales, afterwards Charles II. On the breaking out of the rebellion he returned to Antwerp, and became director of the academy there, where in 1659 he was killed by the accidental discharge of a gun.

WOUVERMANS, PHILIP, was a remarkable and melancholy instance of those mis-fapen and unhappy combinations of talent, industry, and ill-fortune, which have occasionally disgraced the world of connoisseurship. He was the son of an indifferent historical painter, and was born at Haerlem in 1620. Having obtained possession of his father's store of pictorial knowledge, he was placed with John Wynants, the landscape-painter, under whose instruction he soon acquired a considerable degree of power in embodying the creations of his own fancy, and to this acquisition he added much by an attentive study of nature.

There is but little known of his private life. Celebrity, which now attends his name, formed no part of his enjoyments; indeed they appear to have been few, and confined to his affection for and attention to his art and his family, which was numerous. His pictures, beautiful as they are, agreeable in their composition and colour, and exquisite in their finish, exhausted his time without raising him above indigence and obscurity. The more free, slight, and loose works of Peter de Laer, called Bamboccio, absorbed the admiration of the Dutch collectors, while the elegant and delightful productions of Wouvermans remained unnoticed and unknown. Time has adjusted the balance, and the united voice of the tasteful now sheds a lustre over the name of the latter; too late, alas! for his gratification or benefit.

The neglect which he endured, and the severity of labour required to complete so many pictures as he has left, in so high and perfect a degree of finishing, exhausted his health, and he died at the early age of 48; having burnt a short time before his death all his studies and drawings, to prevent, as he declared, his children from being induced to follow a profession which had been but a source of poverty and misery to himself.

The subjects of his pictures are drawn from the common scenes of nature, but are sometimes of a more elevated cast than those chosen by the generality of his compatriots, particularly his hawkings and huntings, where cavaliers and high dames, with appropriate scenery, rich trappings to their horses, and numerous retinues, are introduced with great taste and propriety. His encampments and battles are composed with the same skill and suavity; indeed the latter is a principal characteristic of all his works, whatever be their subjects, from the humble hay-cart to the richest combination of materials which the gay palace, its garden, and splendid adornments, afforded him. Farriers' shops, fairs of horses, travellers on their road, or at inn-doors, &c. &c. were equally rendered agreeable by his delightful arrangements of chiaro-oscuro and of colours, and by the exquisitely firm full touch with which they are executed. His works are numerous, and when in good preservation sell at very considerable prices.

WOUVERMANS, PETER, the younger brother of Philip, was also an artist of considerable talent, though by no means equal to him. He was also born at Haerlem, about the year 1625. He was trained under R. Rogman, but principally followed his brother's style, and adopted his class of subjects. But though his pictures are frequently sold for Philip's, yet they are not so delicate or spirited, and may be easily distinguished from his by a cultivated eye. There

was also another brother, a few years younger than Peter, who followed the same line of art with rather more talent; so that we cannot be surprised at the number of pictures which bear the name of Wouvermans. John died in 1666, at the age of 38.

WOXEN, in *Geography*, a large and noisy current of Sweden, formed by the discharge of the lake of Saima into the Ladoga, which forms a vast cataract about a mile from its mouth.

WOXNA, a town of Sweden, in Helplingland; 40 miles W. of Soderhamn.

WOXTORP, a town of Sweden, in the province of Smaland; 27 miles N.W. of Wexio.

WOYE, a town of Germany, in the principality of Culmbach; 5 miles S.E. of Hof.

WOYTZ, a town of Silesia, in the principality of Neisse; 2 miles E. of Ottmucha.

WRA, a town of Sweden, in the province of Smaland; 48 miles W.S.W. of Wexio.

WRACK. See WRECK.

WRACK, in *Natural History*. See WRECK.

WRACK, in *Agriculture*, a name sometimes given to a marine plant, which is of great utility as a manure. With this plant surgeons sometimes make a cataplasm, by bruising a quantity of it, and applying it in cases of scrofula, or white-swelling, but more particularly glandular tumours. Where this cannot be got, sea-water and oat-meal formed into a poultice have supplied its place. There is no reason why the tumours and ill-conditioned sores of brute animals should not be benefited by similar applications. See WRECK.

It is frequently termed *sea-wrack*, *sea-tangle*, and *sea-oak*. See *SEA-Weed*.

WRAGBY, in *Geography*, a small market-town in the wapentake of Wingrove, Lindsey division of the county of Lincoln, England, is situated at the junction of the turnpike-roads leading from Lincoln to Louth and Horncastle, and is distant 11 miles N.E. by E. from Lincoln, and 144 miles N. by W. from London. George Villiers, duke of Buckingham, who possessed this manor in the reign of Charles II., obtained from that monarch a charter to hold a weekly market on Thursday and two annual fairs, which are now well frequented. Sir Edmund Turnor, who purchased the manor of the duke, erected and endowed an alms-house for six clergymen's widows, and six other destitute persons, for whose use he built a chapel, with an augmentation to the vicarage of 40*l. per annum* for prayers to be read in it twice every day: this chapel was consecrated by bishop Gardiner July 18, 1697. Here is also a free-school, founded and endowed in 1633 by William Hanford, esq. The population of Wragby is stated, in the return of the year 1811, to be 709; the number of houses 103. The manor is now possessed by Edmund Turnor, esq. who has a seat in the adjacent parish of Panton, called Panton-hall, which was built by Hawkmoor, a pupil of sir John Vanbrugh, in the year 1724: considerable additions have been made to it from the designs of Mr. Carr, architect at York; and the adjoining country has been greatly improved by ornamental plantations. Two miles north of Wragby is Halton Lodge, the seat of colonel Caldicot, in whose family the manor of Halton has been vested for several generations.—*Beauties of England and Wales*, vol. ix. Lincolnshire; by J. Britton, F.S.A. 1808.

WRAIN-BOLTS, in *Ship-Building*, are iron ring-bolts, used when planking ships, &c. with two or more fore-lock holes near the end, for taken-in the set, as the plank, &c. works nearer the timbers.

WRAIN-Staves, a sort of stout billets of tough wood, tapered

tapered at the ends so as to go into the ring of the wrain-bolt, to make the sets necessary for bringing-to the planks or thick stuff to the timbers.

WRAM, in *Geography*, a town of Sweden, in the province of Skone; 13 miles W.S.W. of Christianstadt.

WRANGLER, SENIOR, a technical term in the university of Cambridge, for the student who passes the best examination in the senate-house, and confers lasting reputation. They who follow next in the same division are respectively termed second, third, fourth, &c. wranglers. In a similar manner, they who compose the second rank of honours are designated by the titles of first, second, third, &c. optimi. Those of the last order are distinguished by the denominations of first, second, third, &c. junior optimi.

WRANGON, in *Geography*, a small island in the gulf of Finland. N. lat. $59^{\circ} 34'$. E. long. 25° .

WRANNY, a town of Bohemia, in the circle of Schlan; 7 miles N.N.W. of Schlan.

WRANOW. See FRAIN.

WRAPPER, in *Botany*. See VOLVA.

WRASSE, in *Ichthyology*, the name of a fish called by authors *turdus vulgaris*, and by some *linca-marina*, the *sea-tench*, and sometimes *old-wife*.

The wrasse, or *labrus linca* of Linnæus, resembles the carp in figure, and is covered with large scales. Its usual size is about five or six inches in length, and it grows to the weight of four or five pounds: its colour is very variable; red, yellow, and brownish, being very frequently mixed in the scales; and it has five or six longitudinal lines, alternately of a pale yellow, an olive colour, and a dusky red. Its nose is long, and bent upwards, and it has thick and fleshy lips extended over the jaws. Its mouth is small, and its teeth, which are disposed in two rows, the first conic, the second very minute, are not very sharp; in the throat, just before the gullet, are three bones, two above of an oblong form, and one below of a triangular shape; with the surface of each rising into roundish protuberances: these are of singular use to the fish for grinding its shelly food before it arrives at the stomach; the dorsal fin consists of sixteen sharp and spiny rays, and nine soft ones, longer than the others: the pectoral fins are large and round, and composed of fifteen rays, the ventral of six; the first sharp and strong; the anal of three sharp spines, and nine flexible: its tail is rounded at the end, and is formed of fourteen soft branching rays; the membranes of the fins and tails are variegated with red and blue spots, and the anterior rays of the back-fin are prickly. It is caught in plenty on the English shores, and is sold among the poorer sort of people in Wales and Cornwall; but is not esteemed a very delicate fish. It is found in deep water, adjacent to the rocks; it will take a bait, though its usual food is shell-fish, and small crustacea. Willughby's *Hist. Pisc.* p. 320. and Pennant. See LABRUS.

WRASSE, *Bimaculated*, *labrus bimaculata* of Linnæus, has a body pretty deep, and of a light colour, marked in the middle on each side with a round brown spot, and another on the upper part of the base of the tail: the lateral line is incurvated; the branchiostegous rays are six; the first fifteen rays of the dorsal fin are spiny, the other eleven soft, and lengthened by a skinny appendage; the pectoral fins consist of fifteen rays; the ventral of six, the first spiny, the second and third ending in a slender bristle; the anal fin is pointed; the four first rays being short and spiny, the rest long and soft. This is an inhabitant of the Mediterranean.

Mr. Pennant has described some other species of wrasse, as the *trimaculated*, *striped*, and *gibbous*, taken on the coast of Anglesea, and another called *ballan*, numbers of which ap-

pear during summer near Scarborough, which is of the form of the common wrasse, except that between the dorsal fin and the tail it has a considerable sinking; above the nose a deep fulcus; and on the farthest cover of the gills a depression radiated from the centre. Pennant's *Brit. Zool.* vol. iii. p. 246, &c. See LABRUS.

WRATENI, in *Geography*. See FRATING.

WRATH, CAPE, a cape in the N.W. extremity of Scotland, in the parish of Durness, which affords excellent pasture for sheep. In its vicinity are vast caverns.

WRBOWALNOL, a town of Bohemia, in the circle of Koniggratz; 16 miles S.W. of Biezow.

WREAK, or WREKE, a river of Leicestershire, which passes by Melton Mowbray, and runs into the Soar, 7 miles N.E. of Leicester.

WREATH, in *Agriculture*, a small roll formed of any kind of light substance, such as straw, hay, &c. and used for different purposes.

WREATH, in *Natural History*. See TURBO.

WREATH, in *Heraldry*, a roll of fine linen, or silk, (like that of a Turkish turban,) consisting of the colours borne in the escutcheon; placed in an achievement, between the helmet and the crest, and immediately supporting the crest.

WREATH *Stick-Band*, in *Agriculture*, a band formed of any kind of twisted stick, used for tying up fagots, and other such purposes.

WRECK, WRACK, *Sea-WRECK*, or *Sea-OAK*, the *fuscus vesiculosus* of Linnæus, in *Natural History*, a soft, very slippery, marine plant, common among rocks that are left dry at the ebb tide, with leaves somewhat resembling those of the oak-tree; the stalk running along the middle of the leaves, and terminated by watery bladders containing either air or a slippery fluid: the vesicles begin in March to fill with a thin juice; and about the end of July they burst, and discharge a matter as thick as honey.

In some places it is used to manure the ground. In Normandy, and other parts, they burn it; and of the ashes make a kind of soda, or potash, which they use in the making of common green glass, to promote the fusion or vitrification of the other materials. See SEA-WEED.

Dr. Russel relates, that he found this plant an useful assistant to sea-water in the cure of disorders of the glands; that he gave it in powder to the quantity of a drachm, and that in large doses it nauseated the stomach; that by burning in the open air, it was reduced into the black saline powder; which seemed, as an internal medicine, greatly to excel the officinal burnt sponge; which was beneficially used as a dentifrice, for correcting laxities of the gums; and which indicated a remarkable degree of detergent virtue by its effect in cleaning the teeth: that the juice of the vesicles, after standing to putrefy, yielded, on evaporation, an acrid pungent salt, amounting to above a scruple from two spoonfuls; that the putrefied juice, applied to the skin, sinks in immediately, excites a slight sense of pungency, and deterges like a solution of soap; that one of the best applications for dissolving hardness, particularly in the decline of glandular swellings, is a mixture of two pounds of the juicy vesicles, gathered in July, with a quart of sea-water, kept in a glass vessel for ten or fifteen days, till the liquor comes near to the consistence of very thin honey: the parts affected are to be rubbed with the strained liquor twice or thrice a day, and afterwards washed clean with sea-water. Lewis's *Mat. Med.* See ÆTHIOPS *Vegetabilis*.

WRECK, in *Sea Language*, denotes the ruins of a ship which had been stranded or dashed to pieces on a shelf, rock, or lee-shore, by tempestuous weather.

WRECK, *Wreccum*, called also *Ship-WRECK*, or *Ship-WRACK*, in *Law*, &c. is when a ship perishes in the sea, and no man escapes alive out of it.

The civilians term it *naufragium*. The goods in the ship which are brought to the land by the waves belong to the king, or him to whom he assigns the right thereof. Thus, in the Stat. Prærog. Reg. 17 Edw. II. cap. 11. "Rex habebit *wreckum maris* per totum regnum, balænas et sturgesiones captas in mari, vel alibi intra regnum, exceptis quibuslibet privilegiatis locis," &c.

Thus also the matter stood by the ancient common law; but the rigour of the law of wrecks has been gradually softened in favour of the distressed proprietors. Accordingly it was first ordained by king Henry I. that if any person escaped alive out of the ship, it should be no wreck; and afterwards king Henry II. by his charter, May 26, A.D. 1174, declared, that if on the coasts of England, Poictou, Oleron, or Gascony, any ship should be distressed, and either man or beast should escape or be found therein alive, the goods should remain to the owners, if they claimed them within three months; but otherwise should be deemed a wreck, and belong to the king, or other lord of the franchise. This was again confirmed, with improvements, by Richard I., who, in the second year of his reign, not only established these concessions, by ordaining that the owner, if he was shipwrecked and escaped, "omnes res suas liberas et quietas haberet," but also, that if he perished, his children, or, in default of them, his brethren and sisters, should retain the property; and in default of brother or sister, then the goods should remain to the king. And by the law, as laid down by Bracton in the reign of Henry III., if not only a dog (*e. g.*) escaped, by which the owner might be discovered, but if any certain mark were set on the goods, by which they might be known again, it was held to be no wreck. Afterwards, in the statute of Westm. 1, 3 Edw. I. cap. 4, the time of limitation of claims, given by the charter of Henry II., is extended to a year and a day, according to the usage of Normandy; and it enacts, that if a man, a dog, or a cat, escape alive, the vessel shall not be adjudged a wreck. And it is now held, that not only if any living thing escape, but if proof can be made of the property of any of the goods or lading which come to shore, they shall not be forfeited as wreck. The statute farther ordains, that the sheriff of the county shall be bound to keep the goods a year and a day (as in France for one year, agreeable to the maritime laws of Oleron, and in Holland for a year and a half); that if any man can prove a property in them, either in his own right or by right of representation, they shall be restored to him without delay; but if no such property be proved within that time, they then shall be the king's. If the goods are of a perishable nature, the sheriff may sell them, and the money shall be liable in their stead. This revenue of wrecks is frequently granted out to lords of manors, as a royal franchise; and if any one be thus entitled to wrecks, in his own land, and the king's goods are wrecked thereon, the king may claim them at any time, even after the year and the day. In order to constitute a legal wreck, the goods must come to land. If they continue at sea, the law distinguishes them by the barbarous appellations of *jetsam*, *flotsam*, and *ligan*.

Wrecks, in their legal acceptation, are now not very frequent; the owner being seldom unable to assert his property within the year and day limited by law. And in order to preserve his property entire, our laws have made many humane regulations, very opposite in their spirit to those which formerly prevailed in all the northern regions of

Europe, and a few years ago were still said to subsist on the coasts of the Baltic sea; permitting the inhabitants to seize on whatever they could get as lawful prize. To what the reader will find under SALVAGE to this purpose, we shall here add, that all persons who secrete any goods of a wreck shall forfeit their treble value; and if they wilfully do any act whereby the ship is lost or destroyed, by making holes in her, stealing her pumps, or otherwise, they are guilty of felony without benefit of clergy. Moreover, by the statute 26 Geo. II. cap. 19, the plundering of any vessel either in distress, or wrecked, whether any living creature be on board or not, or the preventing the escape of any person that endeavours to save his life, or the wounding of him, with intent to destroy him, or the putting out of false lights in order to bring any vessel into danger, are all declared to be capital felonies, in like manner as the destroying of trees, steeples, or other stated sea-marks is punished, by 8 Eliz. cap. 13. with a forfeiture of 100*l.* or outlawry. Also by the statute of Geo. II. the pilfering of any goods cast ashore is declared to be petty larceny; and many other salutary regulations are made for the more effectually preserving ships of any nation in distress.

By the civil law, to destroy persons ship-wrecked, or prevent their saving of the ship, is capital; and to steal even a plank from a vessel in distress, or wrecked, makes the party liable to answer for the whole ship and cargo. The laws also of the Visigoths, and the most early Neapolitan constitutions, punished with the utmost severity all those who neglected to assist any ship in distress, or plundered any goods cast on shore. Blackst. Com. book i. p. 291, &c.

In divers charters and old writings, it appears that wreck, anciently, not only comprehended goods which came from a perishing ship, but whatever else the sea cast upon land: whether it were precious stones, fish, sea-weed, or the like.

This wreck, in the Grand Customary of Normandy, cap. 17. is called *varech*, and latined *veriscum*; and in some of our ancient charters, *wreche*, *werec*, *werech*, and *scup-werp*, q. d. *sea-upwerp*, of *sea* and *upwerpen*, to cast up.

Shipwreck, in marine insurance, and as it concerns the right of *abandoning*, is generally a total loss. What may be saved of the ship or goods is so uncertain, and depends so much on accident, that the law cannot distinguish this from the absolute destruction of the whole. The wreck of the ship may remain, but the ship is lost. Thus also the goods may remain; but if no ship can be procured, in a reasonable time, to carry them to their place of destination, the voyage is lost, and the adventure frustrated. But the mere *stranding* of the ship is not, of itself, deemed a total loss, so as to intitle the insured immediately to abandon. It is only where the stranding is followed by shipwreck, or in any other way renders the ship incapable of prosecuting her voyage, that the insured is intitled to abandon. If the voyage be lost, this is a total loss, not only of the ship and freight, but also of the cargo, if no other ship can be procured to carry it to its port of destination. Moreover, if a cargo be damaged in the course of the voyage, so that what has been saved is less in value than the amount of the freight, this is clearly a total loss. In case of shipwreck the rule in France is, that the insured may abandon, though the goods be recovered and carried to their place of destination, because goods thus saved are generally in a bad and unmarketable condition. But if the ship become un navigable, the insured cannot abandon the goods, if by any other ship they may be conveyed in time to their place of destination.

As it is reasonable and necessary that the time of the underwriter's responsibility should be limited, this limit is fixed in some maritime states on the continent, within which period after the loss the insured may abandon. In France, Spain, and Holland, the times are limited by law, according to the distance of the place where the loss happens, within which the abandonment must be made. In England there is no time, limited by law, for abandoning: but the courts have adopted a rule better suited to the promotion of commerce, and more likely to prevent frauds, which is this: that as soon as the insured receives advice of a total loss, he must make his election whether he will abandon or not: if he determines to abandon, he must give the underwriters notice of this "within a reasonable time" after the intelligence arrives; and any unnecessary delay in giving this notice will amount to a waiver of his right to abandon; for unless the waiver does some act signifying his intention to abandon, it will be only a partial loss, whatever may be the nature of the case, or the extent of the damage. If by any interference of the underwriters the insured be actually prevented from abandoning, the underwriters are liable for all the loss sustained by the insured to the extent of the sum insured. If the insured determine to abandon, and demand as for a total loss, he is not obliged, as in some foreign countries, to make a formal protest, but merely to give notice of the loss to the underwriters, and of his determination to abandon. The notice of abandonment may be given, either to the underwriter himself, or to the agent who has subscribed for him: and the abandonment ought to be made for the whole of the effects insured, and not for a particular part. The abandonment must be also simple and unconditional; otherwise it will not transfer the entire property to the insurers, which is of the essence of the abandonment. By the abandonment, the insured yields up to the insurers all his right, title, and interest in the ship or goods insured, or what may be saved of them, which, from the notice of abandonment, become the property of the insurers; but the abandonment of the ship does not, as in France, transfer to the insurer the freight she has earned. The abandonment not only intitles the underwriters to all that can be saved of the effects insured; but if compensation be made to the insured for the injury from which the loss arose, this compensation shall go to the underwriters; for when they have paid the loss, they, and not the insured, are the real sufferers. If the ship, after abandonment, arrive safe, the insurers shall have all the profit of the voyage. Nor shall they, on account of the safe arrival of the ship, refuse to pay the sum insured. So if the ship or goods insured happen to be recovered undamaged, after the insurer has paid a total loss, the insurer cannot compel the insured to refund the money, and take back the ship or goods, but the insurer shall stand in his place, and shall have the benefit of salvage. An abandonment once properly made, on sufficient ground, and accepted by the insurers, is absolute and binding upon both parties, and cannot be revoked unless by mutual consent; but if the ground be insufficient, it will be void. In case of shipwreck or other misfortune, the effects that are saved continue, till abandonment, the property of the insured, who is bound in justice, honour, and conscience, to use his utmost endeavours to make the most of what may be rescued from destruction; in order, as much as possible, to lighten the burden of the insurers. To enable him to do this, without prejudice to his right of abandonment, our policies provide, that in case of any loss or misfortune to the insured, their factors, servants, or assigns, shall be at liberty to sue, and labour about the defence, safeguard, and recovery of the goods and merchandizes, and

ship, &c. without prejudice to the insurance; "to the charges whereof, the insurers agree to contribute, each according to the rate and quantity of his subscription." Marshall on Insurance, vol. ii. See *Perils of the SEA*.

WRECK, in *Metallurgy*, a vessel in which the third washing is given to the ores of metals.

In Cornwall, when the tin-ore has been twice washed, they take the head tin, or that part of the tin-ore that lies uppermost, out of the buddle, and throwing it into this vessel, they pour water on it, and work it about with wooden rakes, till it is cleared from whatever other extraneous matter there may still have remained mixed with it, and is, after this, fit for the blowing-house to be run into metal.

WRECK, in *Agriculture*, a term signifying the weeds thrown up by the floods upon the sea-shores; also the dead indigested roots and stems of grass, and other plants in ploughed lands.

WREKIN, in *Geography*, a mountain of England, in Shropshire; about 10 miles E. of Shrewsbury.

WREME, a town of the duchy of Bremen; 5 miles N.N.W. of Carlsburg.

WREN, Sir CHRISTOPHER, in *Biography*, an eminent architect and mathematician, was born in 1632, at the living of his father, who was rector of East Knoyle, in Wiltshire, and finished his education at Wadham college, Oxford, into which he entered in 1646. Before this time, he had given proofs of genius by the invention of astronomical and pneumatic instruments; the former of which he dedicated to his father, at the age of 13, in a copy of elegant Latin verses, together with an exercise "De Ortu Fluminum." He also distinguished himself by the construction of other philosophical instruments; and in 1647 he wrote a treatise on Spherical Trigonometry upon a new plan. In 1650 he graduated B.A., and in 1651 wrote an algebraical tract on the Julian period. In 1653 he was elected fellow of All-Souls' college, and graduated M.A. He was one of the first members of the Philosophical Society at Oxford, from which proceeded the Royal Society, and contributed by his experiments and inventions to the amusement and instruction it afforded; and in 1663 he was elected a fellow of the Royal Society. In 1657 he was chosen astronomical professor at Gresham college; but upon being appointed Savilian professor of astronomy at Oxford, he resigned the former office, and in 1661 returned to the university, which created him doctor of laws. Wren next presents himself to our view as a pre-eminent architect; and thus distinguished, he received a commission in 1663 to prepare designs for the repair of St. Paul's cathedral; and after his return from a tour to France in 1665, with a view to his improvement in architecture, he finished those designs; but whilst they were under consideration, the edifice was destroyed by the fire of London in 1666. This catastrophe afforded him an opportunity of designing and constructing a building altogether new. The contemporary destruction of 50 parochial churches and many public buildings furnished ample scope for the exercise of Wren's talents; and he would have had the honour of re-founding, as it were, a new city, if the design which he laid before the king and parliament could have been accomplished without infringing on the rights of private property. On the death of sir John Denham in 1667, he succeeded to the office of surveyor of the works; and in order to obtain leisure for executing the various works in which he was employed, and more particularly the rebuilding of St. Paul's cathedral, he resigned his Savilian professorship in 1673. In 1674 he received the honour of knighthood, and in the following year the foundation of the new cathedral was laid. For a particular account of this magnificent

magnificent edifice, see the article LONDON. In 1680 sir Christopher's scientific merits caused him to be elected president of the Royal Society. In 1683 he was appointed architect and commissioner for Chelsea college, and in the following year comptroller of the works in the castle of Windsor. In 1685 he was introduced into parliament as a representative of Plympton. To his other public trusts were added, in 1698, that of surveyor-general and commissioner for the repair of Westminster abbey; in 1699 that of architect of Greenwich hospital; and in 1708 that of one of the commissioners for the 50 new churches proposed to be erected in and near the city of London. Having fulfilled all his duties to the 86th year of his age, the administration of 1718 incurred indelible disgrace, by suffering political consideration to have such influence as to deprive him of his place of surveyor to the royal works. The remaining five years of his life were spent in honourable retirement, and devoted to scientific pursuits, and the reading of the Scriptures. It is said that he indulged a very pardonable vanity by being carried once every year to survey St. Paul's cathedral. His life was prolonged to his 91st year, and terminated in consequence of a cold which he caught in coming from Hampton-Court to London, in February 1723. His remains were interred, with suitable funeral honours, under the choir of St. Paul's, and upon his tomb is a concise but very appropriate and expressive Latin inscription, ending "Lector, si monumentum requiris, circumspice." Sir Christopher was twice married, and left one son, a man of learning and piety, and a good antiquary. The edifices constructed by Wren were mostly public, including a royal hunting-seat at Winchester, and the modern part of the palace at Hampton-Court. Some of the most remarkable, besides St. Paul's, are, the Monument, the theatre at Oxford, the library of Trinity college, Cambridge, the hospitals of Chelsea and Greenwich, and of Christchurch, London, the church of St. Stephen, Walbrook, those of St. Mary-le-Bow, St. Michael, Cornhill, and St. Bride, distinguished by their steeples, and the great campanile of Christchurch, Oxford. Of the rank which he occupied as a man of science, we may form some judgment from the succeeding concise detail of his performances, and more particularly from the testimony of sir Isaac Newton, who, in his "Principia," joins the names of Wren, Willis, and Huygens, and characterizes them as "hujus ætatis Geometrarum facile principes." As to his moral character, it is said to have been worthy of his intellectual eminence; as with great equanimity, he was pious, temperate, modest, and communicative of his knowledge; and few men seem to have been more generally esteemed by their contemporaries. With regard to his architectural skill and attainments, a very competent judge, being himself of the profession, says, that he possessed an inexhaustible fertility of invention, combined with good natural taste and profound scientific knowledge; and that his talent was particularly adapted to ecclesiastical architecture, which afforded domes and towers to his picturesque fancy; while, in his palaces and private houses, he has sometimes sunk into a heavy monotony, as at Hampton-Court and Winchester. Among the rich variety of Wren's towers, steeples, and spires, many are truly elegant. The church of St. Stephen's, Walbrook, exhibits a deviation from common forms equally ingenious and beautiful. The Monument is grand and simple. At Greenwich, his additions to the original work of Inigo Jones are singularly grand and beautiful. Upon the whole, sir C. Wren's architecture is perhaps the perfection of that modern style which, with forms and modes of construction essentially Gothic, adopts for the decorative

part the orders and ornaments of antiquity. Biog. Brit. Walpole's Anecd. Gen. Biog.

WREN, or *Jenny-Wren*, in Ornithology, the *passer troglodytes* of Gefner, and the *motacilla troglodytes* of Linnæus, has the head and upper part of the body of a deep reddish-brown; above each eye is a stroke of white; the back, and coverts of the wings and tail, are marked with slender, transverse, black lines; the quill-feathers with bars of black and red; the throat is of a yellowish-white; the belly and sides crossed with narrow dusky and pale reddish-brown lines; and the tail is crossed with dusky bars. Pennant.

This bird, though very small, is of a very cheerful disposition, and has a very agreeable voice, which he throws out with great cheerfulness and sprightliness, usually cocking up his tail all the time he is singing, and continues his song through the winter, except during the frosts. See SONG of Birds.

The female breeds twice in the year, first in the latter end of April, and afterwards in the middle of June. The nest is usually placed among clusters of moss and ivy, in such a manner that it is very hard to discover it. It is made of dry moss and leaves put together in a very artificial manner, being closed all round except for a small hole left to go in and out at. They lay a great number of eggs, not less than eighteen; and it has been often found that they all hatch except one or two; and thus sixteen young ones have been found together in the nest. These are brought up so well as to shift for themselves by the end of May; and then another brood is provided for by the middle of the month following. The young ones may be easily raised. They should for this purpose be taken out of the nest at about fourteen days old, and fed with sheep's, calf's, or ox's heart, cut small, with eggs minced among it. When they are able to peck this meat for themselves, they may be put into cages; but they must still be fed for some days, lest they should neglect themselves, and die of hunger after the greatest part of the trouble is thus over. See MOTACILLA *Troglodytes*.

When they are grown up, they may be fed with paste, and will need no more heart. Afterward it will be a great feast to them to give each a spider or two at once in two or three days; and after they attain full age, they may either be left to sing their own wild notes, which are very agreeable, or if it be desired that they should whistle tunes, they will easily be taught it. Ray and Pennant.

WREN, *Crested*, or *Golden-Crested WREN*, *regulus cristatus*, or *motacilla regulus* of Linnæus, the name of a very beautiful little bird, the smallest of all the British birds. Its whole weight is not more than seventy-six grains; and the crown of its head is adorned with a very beautiful saffron-coloured or orange-red spot, which is called its crest, and by some its crown, and from this golden crown the bird has obtained the name of the *regulus*, *tyrannus*, *basileus*, and other appellations of royalty. This beautiful scarlet mark on the head is bounded on each side by a fine yellow line. The bill is dusky; the feathers of the forehead are green; from the bill to the eyes is a narrow white line; the back and hind part of the neck are of a dull green; the coverts of the wings dusky, edged with green, and tipped with white; the quill-feathers and tail dusky, edged with pale green; the throat and lower part of the body white, tinged with green; the legs are of a dull yellow colour; and the claws are very long.

This bird frequents woods, and is found principally in oak-trees. It is common about the Peak in Derbyshire, and is seen in autumn as far north as the Shetland isles, but quits that country before winter. It lays six or seven eggs,

not larger than peas. This bird has been observed suspended in the air for a considerable time over a bush in flower, whilst it sung very melodiously. The note does not much differ from that of the common wren, but is very weak. Ray and Pennant. See *MOTACILLA Regulus*.

WREN, *Yellow*. See *LUTEOLA*, and *MOTACILLA Trochilus*.

WRENCH. See *STRAIN*.

WRENTHAM, in *Geography*, a town of the state of Massachusetts, in the county of Norfolk, containing 2478 inhabitants; 23 miles S.W. of Boston.

WRESTBALKING, in *Agriculture*, the operation of turning over upon or covering a balk or rib of whole un-moved ground, by a broad furrow-slice, in the view of rendering the land more mellow and porous. The term is chiefly used in the eastern districts of the country.

WRESTLING, a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent to the ground.

Wrestling, *palastra*, is an exercise of very great antiquity and fame. It was in use in the heroic age; witness Hercules, who wrestled with Antæus.

It continued a long time in the highest repute, and had very considerable rewards and honours assigned it at the Olympic games. It was the custom of the athletes, or wrestlers, to anoint their bodies with oil, to give the less hold to their antagonist. See *PALÆSTRA*.

Ablancourt observes, that Lycurgus ordained the Spartan maids to wrestle in public, quite naked, to break them of their too much delicacy and niceness; to make them appear more robust, and familiarize the people, &c. to such nudities.

A wrestling match, or *neobering*, is a very common diversion in the Mandingo countries of Africa. It is exhibited at the "Bentang," which is a large stage found in each town, that answers the purpose of a public hall or town-house: it is composed of interwoven canes, and is generally sheltered from the sun by being erected in the shade of some large tree. It serves also for a kind of lounging place, where the indolent and unemployed assemble to smoke their pipes, and talk over the news of the day.

At the wrestling match, the spectators arrange themselves in a circle, leaving the intermediate space for the wrestlers, who are strong, active, young men, trained up from infancy to this sort of exertion. Being stripped of their clothing, except a short pair of drawers, and having their skin anointed with oil, or *shea* butter, they approach each other on all fours, parrying with and occasionally extending a hand for some time, till at length one of them springs forward and catches his rival by the knee. Great dexterity and judgment are now displayed; and the contest is at length decided by superior strength. The combatants are animated by the music of a drum, which serves also in some measure to regulate their motions. The wrestling is succeeded by a dance, in which many performers assist, all being provided with little bells fastened to their legs and arms; their motions being regulated by the drum, beaten by a crooked flick, which the drummer holds in his right-hand, occasionally using his left to deaden the sound, and thus vary the music. The drum is also used to keep order among the spectators; and when the wrestling match is about to begin, the drummer strikes what is understood to signify "ali bæ fee," fit all down; upon which the spectators immediately seat themselves; and when the combatants begin, he strikes "amuta, amuta," *i. e.* take hold, take hold.

VOL. XXXVIII.

WRETESTA, in *Geography*, a town of Sweden, in Sudermannland; 36 miles N.W. of Nykioping.

WRETSTORP, a town of Sweden, in the province of Nericia; 16 miles S.W. of Orebro.

WRETWEED, in *Agriculture*, a name sometimes given to wart-weed or sun-spurge, a troublesome weed in fields. See *WEED*.

WREXHAM, in *Geography*, a market-town in the hundred of Bromefield, towards the east corner of the county of Denbigh, North Wales, is situated 25 miles E.S.E. from Denbigh, 11 $\frac{3}{4}$ S.S.W. from Chester, and by the road through Whitechurch 176 N.W. from London. The parish of Wrexham is extensive and populous, and comprises 14 townships. By the returns of 1811, the population of the whole amounted to 19,495, and the houses to 4142.

Wrexham is a place of considerable antiquity, for it is mentioned in the Saxon Chronicle by the name of Wrigh-teletham. Although belonging to Cambria, yet being separated by the ancient trench called Offa's Dyke, it came to be ranked as appertaining to the great internal district of England, Mercia. In the reign of Edward I., the town and the lordship were granted to earl Warren; and as early as the reign of Henry VIII., the town was known for its trade, particularly for its buckle-makers. Wrexham is noted for its fairs, one of which continues for nine days, for the sale of Welsh flannels, cattle, Irish linens, English woollens, ironmongery, &c. The weekly markets are kept on Monday and Thursday. The church of Wrexham is the most remarkable and most ornamented building of its kind in North Wales. It was erected in 1472, but the tower was not finished till 1506. It consists of a nave, with side aisles, and a chancel; the whole length being 178 feet, and the breadth 72: the tower rises to the height of 135 feet; the aisles are separated from the nave by clustered columns supporting pointed arches; the ceiling is composed of oak, in imitation of groined stone. In the town is a free-school for educating twelve boys. Two miles west from Wrexham is Borsham, which is noted for the great iron-furnaces of Messrs. Wilkinson. Notwithstanding the difficulties in the beginning, the works are now among the greatest in the kingdom. The machinery employed is very ingenious; and every article of cast-iron, from cannon down to kitchen utensils, is fabricated in great numbers. Iron-stone and coal are plentiful in the neighbourhood; and at a short distance is a productive lead-mine. The Ellesmere canal between Shrewsbury and Chester passes half a mile to the west of Wrexham. Two miles more to the westward is the celebrated intrenchment called Offa's Dyke, which extended from the river Wye in Monmouthshire on the south into Flintshire on the north; and is supposed to have been formed by that Saxon chief of Mercia, to defend his country from the native Britons, who had retired among the mountains of Wales. On the east side of Wrexham is Wat's Dyke, another intrenchment of the same kind, probably intended for a similar purpose, but unconnected with the work of Offa.

About seven miles S.S.W. from Wrexham is Ruabon, a village with a respectable church, containing the monuments of the ancient families of Williams and Wynn; one in particular for the first sir Watkin, who died in 1749, is a distinguished production of Rysbrack. The learned Dr. David Powell, the translator and editor of sundry historical works relative to Wales, was a native and vicar of Ruabon, where he died in 1590. On the east side of the village is the gate leading to the park and mansion of Wynnistay, the seat

of sir Watkin Williams Wynn, bart. The road runs through an avenue of trees of uncommon growth, in a straight line for a mile, to a spacious lawn, on which stands the house. Erected at different periods, and in different styles of architecture, Wynnstay-hall is more distinguished for size and irregularity than for beauty of architecture. The new parts erected by the first baronet, although only a portion of the design, form a plain, substantial, comfortable place of residence; the older parts are chiefly appropriated to menial purposes. The interior comprehends some spacious apartments, in which are a few valuable portraits, particularly one by Vandyke of sir Richard Wynn, who attended Charles I. on his romantic matrimonial adventure to Spain. Adjoining to the house is a small building, formerly used as a theatre. The park, from the ancient intrenchment Wat's Dyke which traverses it, was formerly called Wat-stay; but when the heiress married sir John Wynn, who inclosed the grounds in 1678 with a stone-wall, the name was changed to its present appellation. The grounds are not greatly diversified, but they are well wooded, and favourably situated for prospects. On an eminence stands a fluted stone column, 100 feet high, on a plinth 16 feet square, accessible to the summit by an internal stair-case. It was erected in memory of the late baronet by his mother, with this simple but eloquent inscription: "Filio optimo mater cheu! superstes." Near the park the river Dee winds through Nant-y-Bele, or the dingle of the Marten, a place of great natural romantic beauty. Caer-ddin in this parish, commonly called Garthen, is a strong British post on a lofty hill, at no great distance from Offa's Dyke. It is formed by a rampart and ditch, in some parts double, and the inner consisting of a thick wall. The area, containing about four acres, exhibits vestiges of ancient buildings.—*Beauties of England and Wales, Denbighshire*, by the Rev. J. Evans, 8vo. London, 1812.

WRIETZEN. See BRIETZEN.

WRIGHT, EDWARD, in *Biography*, an English mathematician, flourished in the latter part of the 16th and beginning of the 17th century. Of his private history little is known, except some few particulars that may be collected from the Latin memoirs of his life, preserved among the annals of Gonville and Caius college in Cambridge. This year (1615) died, it is said, at London, Edward Wright, of Garvelton in Norfolk, formerly a fellow of this college, much respected for the integrity and simplicity of his manners, and also famous for his skill in the mathematical sciences. He was the first undertaker of the difficult but useful work, by which a little river is brought from the town of Ware, in a new canal, to supply the city of London with water; but by the tricks of others he was prevented from completing it. Nor was he inferior to the most ingenious mechanic in the construction of instruments, either of brass or of any other matter. He, it is said, taught Iodocus Hondius the method of constructing his geographical charts, though Hondius concealed his name, that he might arrogate to himself the honour of the invention. Of this act of injustice, Wright complained in the Preface to his "Treatise of the Correction of Errors in the Art of Navigation," a work composed with excellent judgment, and after long experience, to the great advancement of naval affairs. For his improvement of this art he was appointed mathematical lecturer to the East India Company; and he read lectures, for which he was allowed a yearly salary of 50*l*. This office he discharged with great reputation, and much to the satisfaction of his hearers. He published, in English, a book on the doctrine of the sphere, and another

concerning the construction of sun-dials. He also prefixed an ingenious preface to the learned Gilbert's book on the load-stone. By these and other writings he transmitted his fame to the latest posterity. It is added, whilst he was a fellow of this college, he was called forth to the public business of the nation by the queen, about the year 1593, or, according to other accounts, 1589. He was ordered to attend the earl of Cumberland in some maritime expeditions; of one of which he gave a faithful account, under the form of a journal or ephemeris, prefixing to it an elegant hydrographical chart of his own invention. His posthumous work, which was an English translation of the book of logarithms, then lately discovered by lord Napier, a friend of Mr. Wright, was published soon after his death by his son Samuel Wright, a scholar of the above-named college. Death prevented the execution of several other designs which he had formed. Of him it may be truly said, that he studied more to serve the public than himself; and though he was rich in fame and in the promises of the great, he died poor, to the scandal of an ungrateful age. To the preceding extracts from the memoirs above cited, we may add, that Mr. Wright first discovered the true method of dividing the meridian line, according to which Mercator's charts are constructed (see CHART), and upon which his sailing is founded. An account of it was sent from Cambridge to Mr. Blondville, who published it among his exercises in 1594; and in 1597 a demonstration of it was given by the Rev. Mr. William Barlowe, in his "Navigator's Supply." In 1599 Mr. Wright published "The Correction of certain Errors in Navigation," written many years before, and shewing the reason of his division of the meridian, the manner of constructing his table, and its uses in navigation, &c. &c. In 1610 he dedicated a second edition to his royal pupil, prince Henry, with farther improvements, and an excellent method for determining the magnitude of the earth. To his other works, comprehending an account of his various discoveries, tables, and improved instruments for observation, we shall add his tract on navigation, entitled "The Haven-finding Art." It is said that he constructed, for the use of prince Henry, a large sphere with curious movements, serving by spring-work to exhibit the motions of the whole celestial sphere, the particular systems of the sun and moon, their circular motions, places, and possibilities of eclipsing each other. (See ORRERY.) This sphere was overlooked in the time of the civil wars, and found among dust and rubbish in 1646 by sir Jonas Moore, who was at the expence of restoring it to its original state, and deposited it at his own house in the Tower, among other mathematical instruments. Preface to Robertson's Navigation. Hutton's Math. Dict.

WRIGHT, RICHARD, was a native of Liverpool, and born about the year 1735. He was bred to the humble occupation of a house and ship painter, but exerted his talents in painting sea views, and obtained for his encouragement the premium offered in 1764 by the society for the encouragement of arts, &c.; and in 1766 he gained another premium of fifty guineas, for a picture which had the greater credit of being most beautifully engraved by Woollett, and is known under the name of the "Fihery." He died about 1775.

WRIGHT, JOSEPH, one of our earliest painters of celebrity in this age of restoration of the art. He was born at Derby in 1734, and thence obtained the name of Wright of Derby, to distinguish him from R. Wright mentioned above. He came to London to study with Hudson, but afterwards established himself at his native place, and had very considerable

siderable encouragement as a portrait-painter, though his style was dry and too minute. He gained much more reputation by painting scenes of fire and candle-light, and indeed stood unrivalled in that way till Louthembourg subsequently appeared. His pictures of a forge and of a blacksmith's shop, exhibited with the society of artists about the year 1765, established his reputation. In 1773 he visited Rome, and Italy generally, and was absent two years. In 1782 he was elected an associate of the Royal Academy, but resigned his diploma soon after, on Mr. Garvey's being preferred to him in an election for an academicians; though he continued occasionally to exhibit with the academy. He had great industry and professional skill, living very much apart from the world. This enabled him to produce many pictures, and in 1785 he made an exhibition of twenty-four pictures of his own painting at the great room under the Piazza Covent-garden, one of which was a large work representing the destruction of the floating batteries before Gibraltar. His style in all his works was peculiar to himself, somewhat dry, yet not void of richness, and his drawing coldly correct. One peculiarity marks his pictures, and renders them easily distinguishable, especially those in which the illumination proceeds from the moon or fire. He prepared his cloths or grounds with rough surfaces, caused by sand sifted or strewed upon them; and then when he had painted his scene, he dragged his pallet-knife, covered with the colour of the light, across the picture, when the colour adhering to the projections on the surface, gave the glitter which characterizes that kind of illumination, and he toned the parts to due relief by glazings. No one ever gave the exact tone of moon-light so completely as Wright of Derby. He died in 1797, aged 63.

WRIGHT, *Mifs*, a vocal apprentice to Michael Arne, the natural son of Dr. Arne. She had a sweet, spirited, and active voice, but was so young in music, that she learned the parts which she had to perform on the stage, after she was too hastily engaged at Drury-lane, by her ear. The first part assigned to her in that theatre was Leonora, in Bickerstaff's Padlock, in which the airs, as set by Dibden, were so pleasing, and so much on the Italian model, that they established her in the favour of the town. But the air "Say little foolish fluttering thing" was never sung in such a brilliant and captivating manner by any other singer.

In 1766 she appeared in the Cunning Man, Rousseau's Devin de Village, translated *totidem syllabis*, and adapted to his original music by the author of this article, in which she pleased extremely.

Soon after this, the apprentice was exalted into the wife of her master, the *serva padrona*, and sung with great applause in Cymon, and several of his and other composers' compositions that were performed at Drury-lane; and, if we remember right, in the summer she sung in Mary-le-bone gardens. But the town was so fond of hearing her, and the produce of her talents so alluring to her husband, that she may truly be said to have sung herself to death; or, like the swans of old in the Po, to have died singing. The truth is, that her ignorance of music made it necessary for her to sing at home, in rendering herself perfect in her parts, ten times more than she did in public, which brought on a pulmonary complaint, and prematurely put an end to her existence in 1770, at the age of 22, to the grief of her friends, and great regret of the public.

WRIGHT, in *Geography*, a town of Virginia; 44 miles W. of Richmond.

WRIGHT'S TOWN, a township of Pennsylvania, in the county of Bucks, with 562 inhabitants; 24 miles N. of Eatton.

WRIGHTIA, in *Botany*, is dedicated by Mr. Brown to his much-respected friend William Wright, M.D. fellow of the royal societies of London and Edinburgh, and associate of the Linnæan society, "whose ardour in the pursuit of botanical knowledge," says Mr. Brown, "even while engaged in extensive medical practice in the island of Jamaica, has long entitled him to this mark of distinction." We heartily concur in this sentiment, and cannot but regret that Dr. Swartz did not retain for this purpose what he has called MERIANA. (See that article.)—Brown in Tr. of the Wernerian Soc. v. 1. 73. Prodr. Nov. Holl. v. 1. 467. Ait. Hort. Kew. v. 2. 68. (Nerium; Gærtu. t. 117.)—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Convolvutæ*, Linn. *Apocineæ*, Juss. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five small, rounded, bluntish segments, with five or ten internal scales at the outside of the base of the corolla, permanent. *Cor.* of one petal, falver-shaped: tube cylindrical, various in length: limb in five oblong, spreading, oblique segments, as long as the tube, or longer: mouth crowned with ten divided scales, shorter than the limb. *Stam.* Filaments five, thread-shaped, short, inserted into the throat of the corolla; anthers arrow-shaped, pointed, prominent, cohering by their middle part to the stigma. *Pist.* Germens two, superior, roundish, cohering; style one, thread-shaped, the length of the tube, dilated at the apex; stigma contracted. *Peric.* Follicles two, almost cylindrical, either distinct or cohering, pointed, erect. *Seeds* numerous, inserted into the margins of each follicle, oblong, imbricated downwards, crowned at the lower extremity with silky hairs, directed towards the base of the seed-vessel.

Ess. Ch. Corolla oblique, falver-shaped; mouth crowned with ten divided scales. Stamens prominent. Follicles two, erect. Seeds imbricated downward, hairy at the lower extremity.

A genus of upright shrubs, or small trees, natives of the East Indies, Ceylon, the Malay archipelago, or the tropical part of New Holland. Their leaves are opposite. *Flowers* white, corymbose, nearly terminal. *Albumen* none. *Embryo* white, turning rose-coloured by immersion in warm water; *cotyledons* involute longitudinally. *Brown.*

1. *W. antidysenterica*. Oval-leaved Wrightia. Br. n. 1. Ait. n. 1. (Nerium antidysentericum; Linn. Sp. Pl. 306, excluding Rheede's synonym. Willd. Sp. Pl. v. 1. 1236. N. n. 107; Linn. Zeyl. 45. N. indicum, filiquis angustis, erectis, longis, geminis; Burm. Zeyl. 167. t. 77.)—Leaves obovate-oblong, short-pointed, smooth. Corymbs mostly terminal. Tube of the corolla six times as long as the calyx. Follicles distinct.—Native of Ceylon. A handsome erect shrub, with numerous branches. *Leaves* on short stalks, spreading, two inches, or two and a half, long. *Tube* as well as *limb* of the *flowers* each an inch in length. *Follicles* thrice as long, a little swelling upwards; their points converging. *Brown. Burmann.*

2. *W. zeylanica*. Lanceolate-leaved Wrightia. Br. n. 2. (Nerium zeylanicum; Linn. Sp. Pl. 306. Am. Acad. v. 4. 309. Willd. Sp. Pl. v. 1. 1236. Apocynum arborescens, nerii flore minus; Burm. Zeyl. 23. t. 12. f. 2.)—Leaves oblong-lanceolate, blunt-pointed, smooth. Corymbs terminal. Tube of the corolla four or five times as long as the calyx. Follicles distinct.—Native of Ceylon. Our specimen was given to Linnæus by Burmann. The branches are long and straight, round, purplish. *Leaves* smaller than the last, about an inch and a half long, with more or less of a linear blunt point. *Flowers* like the preceding, but, according to Mr. Brown, the *tube* is shorter in proportion.

3. *W. tinctoria*. Dyer's Wrightia. Br. n. 3.—"Leaves elliptic-

elliptic-lanceolate, or ovate, pointed, smooth. Branches and corymbs divaricated. Tube of the corolla twice the length of the calyx. Follicles distinct."—Found by Koenig and Roxburgh in the East Indies. We received from Dr. Roxburgh in 1789, by the name of *Nerium antidysentericum*, specimens which answer to the above characters, except that the *tube* is not at all longer than the *calyx*; the *limb* moreover appears purplish, and is clothed on both sides with fine pubescence. This plant must be known to Mr. Brown, and perhaps is one of the undescribed species of which he makes mention.

4. *W. pubescens*. Downy Wrightia. Br. n. 4. Prodr. n. 1.—"Leaves elliptic-oblong, pointed, downy as well as the calyx. Corymbs erect. Tube of the corolla scarcely longer than the calyx. Follicles combined."—Gathered by Mr. Brown in the tropical part of New Holland, and in the isle of Timor, near Coepang.

This author speaks of some other species, of which he has not yet published either characters or names, and which are not known to us. *Nelum-Pala*, Rheede Hert. Mal. v. 9. 5. t. 3 and 4, is presumed to belong to the present genus.

WRIGHTSBOROUGH, in *Geography*, a settlement in the state of Georgia, on a branch of the Savannah; 30 miles W. of Augusta.

WRING-HOUSE, in *Rural Economy*, a name sometimes applied to the place for making cyder in, in the southern districts.

WRINGLE-TAIL, a name given by the people of several parts of England to the *curvicauda*, a species of bee-fly, very much resembling the bee in shape, but having only two wings and no sting. It is very troublesome to horses, but does not suck their blood, but only lays its eggs in their skins: it is called in other countries the *wbame* and the *barrel-fly*.

WRINGTON, in *Geography*, a market-town in the hundred of Brent-with-Wrington, in the county of Somerset, England, is situated to the S.W. of the Mendip hills, at the distance of 6 miles N.N.E. from Axbridge, and 129 miles W. from London. The streets are irregularly built, and most of the houses are thatched. A weekly market, by a very ancient grant, is held on Tuesday; and here is an annual fair. In the market-place are the ruins of a cross. The church, a spacious edifice, 120 feet in length and 52 in width, consists of a nave, chancel, side aisles, and a porch. The tower, at the west end, is 140 feet high to the top of the battlements, which are adorned with four turrets, one at each corner, and sixteen elegant pinnacles fifteen feet in height. The church contains several ancient and modern monuments. One is of peculiar beauty: it is built of white and Sienna marble, and was erected in memory of Dr. Henry Waterland, prebendary of Bristol, and above fifty years minister of this parish, where he constantly resided: he died March 27, 1779. In the town is a free-school for six boys and as many girls. In the return of the year 1811, the population of the parish is enumerated as 1109, the number of houses as 183. Wrington is distinguished by being the birth-place of the celebrated philosopher, John Locke: he was born 1632, in an old thatched house, still standing on the north side of the church-yard: he died October 28, 1704. See LOCKE, JOHN.—Collinson's History of Somersetshire, vol. i. 1791.

WRIST, CARPUS, in *Anatomy*. See EXTREMITIES.

WRIST, *Fracture, Ligaments, and Luxation of*. See the respective articles.

WRIST, in the *Manege*. The bridle wrist is that of the cavalier's left-hand. A horseman's wrist and his elbow

should be equally raised, and the wrist should be two or three fingers above the pommel of the saddle. To ride a horse from hand to hand, *i. e.* to change hands upon one tread, you need only to turn your wrist to that side you would have the horse to turn to, without advancing your hand. But if your horse stops, you must make use of both your legs. See HAND and LEGS.

WRIT, formed from the Saxon *writan*, to write, *Breve*, in *Law*, a precept of the king in writing, under seal, issuing out of some court to the sheriff or other person, whereby any thing is commanded to be done, touching a suit or action, or giving commission to have it done: as, the summoning of a defendant, taking a distress, redressing a disseisin, or the like. Or, according to Fitzherbert, a writ is a formal letter of the king in parchment, sealed with a seal, and directed to some judge, officer, or minister, &c. at the suit or plaint of a subject, requiring to have a thing done, for the cause briefly expressed, which is to be discussed in the proper court according to law. See BREVE, BRIEF, and PRECIPE.

Writs are variously divided, and in various respects. Some, with regard to their order, or manner of granting, are termed *original*, and others *judicial*.

WRITS, *Original*, are those sent out of the high court of chancery, to summon the defendant in a personal or tenant in a real action; either before the suit begins, or to begin the suit by it. See ORIGINAL.

Royal writs are held to be demandable of common right, on paying the usual fees; for any delay in the granting of them, or setting an unusual or exorbitant price upon them, would be a breach of Magna Charta, cap. 29. "Nulli vendemus, nulli negabimus, aut differemus justitiam vel rectum."

Original writs are either optional or peremptory, or, in the language of our law, they are either a *precipe*, or a *scite fecerit securum*.

WRITS, *Judicial*, are those sent by order of the court where the cause depends, upon emergent occasions, after the suit begins.

Judicial writs are distinguished from *original*, in that their teste bears the name of the chief-justice of that court whence they come; whereas the *original* say, *teste meipso*, in the name or relating to the king.

The *original* writ is always made returnable at the distance of at least fifteen days from the date or *teste*, and upon some day in one of the four terms: and all *judicial* writs, being grounded on the sheriff's return, must respectively bear date the same day on which the writ immediately preceding was returnable. See PROCESS.

Judicial writs, if erroneous, may be amended: whereas *original* writs are not amendable, if the error be by default of the party who gave instruction; yet a new *original* may be taken out, where it is not amendable.

Writs are also distinguished, according to the nature of the action, into *real* and *personal*.

Real, are either touching the possession, called *writs of entry*; or the property, called *writs of right*. See RECTO.

Personal writs, are those relating to goods, chattels, or personal injuries.

To which may be added *mixt* writs, for the recovery both of the thing and damages.

Some writs, again, are at the suit of the party; some, of office; some, ordinary; some, of privilege. A writ of privilege is that which a privileged person brings to the court for his exemption, by reason of some privilege which he enjoys.

But the most common writs in daily use are, in debt, detinue,

tinue, trespass, action upon the case, account, and covenant, &c. which, as well as others, must be rightly directed, or they will be naught.

Writs may be renewed every term, until a defendant is arrested; but in the court of king's bench, if the *latitat* be not renewed in five terms, a new writ is to be taken out, and the plaintiff is not allowed to renew the old one.

The sheriff's bailiffs cannot execute a writ directed to the sheriff, without his warrant; and if several persons are included in a writ (for four defendants may be in one writ), there must be several warrants from the sheriff to execute the same. All writs are to be returned and filed in due time, to avoid *post-terminum*.

Attachment lies against sheriffs, &c. for not executing a writ, or for doing it oppressively by force, extorting money on it, or not doing it effectually, by reason of any corrupt practice.

WRIT of *Appraisement*, a writ issued out of court for the valuation of goods seized as forfeited to the crown; or goods taken as prize of war, or found wrecked, flotsam or jetsam.

Several seizures by several persons not amounting to 100*l.* may be included in one writ. (Bunbury, p. 63.) And a new writ was ordered where the first appraisement was too high. (Ibid. 49. 185.) They are also required to specify the goods particularly, p. 89.

WRIT of *Affise*. See ASSISE.

WRITS of *Affisance*, are writs issued out of the exchequer, to enable officers to enter ships, houses, warehouses, and other places, to search for smuggled or prohibited goods. They are directed to be granted by 13 & 14 Car. II. c. 11. and are issued on oath, that there is strong presumption to believe goods of those kinds are harboured; but if they are executed in the night, the officers must be accompanied by a peace-officer.

WRIT of *Capias*. See CAPIAS.

WRIT of *Delivery*, a writ directing the delivery of goods out of the king's possessions, either by verdict or by consent. They cannot be issued till the information is in court (Bunbury, p. 27.); and they are discretionary in the court. (Ibid. p. 196.) A writ was granted out of the exchequer for watches, because the springs and steel-work were liable to rust (p. 74.); but it was refused for tobacco-stalks, because they were directed to be burnt. (P. 196.) A writ was also refused in Ladd's and in Thomsett's case, in the same court, for coins; the former reported, the latter not reported.

WRIT of *Distringas*. See DISTRINGAS.

WRIT of *Election to Parliament*. See PARLIAMENT.

WRIT of *Entry*. See ENTRY.

WRIT of *Inquiry of Damages*, a judicial writ that issues out to the sheriff upon a judgment by default, in an action of the case, covenant, trespass, trover, &c. commanding him to summon a jury to enquire what damages the plaintiff hath sustained, *occasione premissorum*; and when this is returned with the inquisition, the rule for judgment is given upon it; and if nothing be said to the contrary, judgment is thereupon entered. 2 Lill. Abr. 721.

WRIT of *Mainprise*. See MAINPRISE.

WRIT of *Neifty*. See NEIFTY.

WRIT of *Rebellion*. See COMMISSION of *Rebellion*.

WRIT of *Right*. See RECTO.

WRITS *Vicountiel*. See VICOUNTIEL.

WRIT, *Action of a*. See ACTION.

WRIT, *Appeal by*. See APPEAL.

WRIT, *Attachment by*. See ATTACHMENT.

WRIT, *Continuance of a*. See CONTINUANCE.

WRITER of the *Tallies*, an officer of the exchequer, being clerk to the auditor of the receipt, who writes upon the tallies the whole letters of the tellers' bills. See TALLY and EXCHEQUER.

WRITING, SCRIPTURA, the art or act of signifying and conveying our ideas to others, by letters or characters visible to the eye.

Or, writing may be defined to be the art of exhibiting to the sight the conceptions of the mind, by means of marks or characters significant of the sounds of language, which enable us to transfer ideas from the eye to the ear, and *vice versa*.

Written characters are of two sorts: they are either signs for things, or signs for words. Of the former sort, are the pictures, hieroglyphics, and symbols, employed by the ancient nations; of the latter sort, are the alphabetical characters now employed by all Europeans. Pictures were, undoubtedly, the first essay towards writing; accordingly, we find in fact, that this was the only sort of writing known in the kingdom of Mexico, when America was first discovered. By historical pictures, the Mexicans are said to have transmitted the memory of the most important transactions of their empire. (See Warburton's *Divine Legat. of Moses*, vol. ii. part i. p. 67, &c. vol. iii. p. 73. Robertson's *Hist. Am.* vol. iii. p. 203, &c. and Appendix, note 26. p. 440. edit. 3vo.) But as pictures could do no more than delineate external events, without exhibiting their connections, describing such qualities as were not visible to the eye, or conveying any idea of the dispositions or words of men, there arose in process of time, for supplying this defect, the invention of hieroglyphical characters; which may be considered as the second stage of the art of writing.

Hieroglyphics (which see) consist in certain symbols, which are made to stand for invisible objects, on account of an analogy or resemblance which such symbols were supposed to bear to the objects. Among the Mexicans were found some traces of hieroglyphical characters, intermixed with their historical pictures. But Egypt was the country where this sort of writing was most studied, and brought into a regular art. However, this sort of writing could be no other than enigmatical and confused, in the highest degree; and must have been a very imperfect vehicle of knowledge of any kind.

As writing advanced from pictures of visible objects to hieroglyphics, or symbols of things invisible; from these latter it advanced, among some nations, to simple arbitrary marks which stood for objects, though without any resemblance or analogy to the objects signified. Of this nature was the method of writing practised among the Peruvians; who made use of small cords, of different colours, and by knots upon these, of various sizes, and differently arranged, contrived signs for giving information, and communicating their thoughts to one another. Of this nature, also, are the written characters which are used to this day in China. The Chinese have no alphabet of letters, or simple sounds, which compose their words; but every single character which they use in writing is significant of an idea: it is a mark which stands for some one thing or object, and consequently the number of these characters must be immense. This CHINESE writing, (which see,) probably began, like the Egyptian, with pictures and hieroglyphical figures; which figures being, in their progress, abbreviated in form, for the sake of more easily writing them, and greatly enlarged in number, passed at length into those marks or characters which they now use, and which have spread themselves through several nations of the East. For it is said, that the Japanese, the Tonquinese, and the Corocans, who
speak

Speak different languages from one another, and from the inhabitants of China, use the same written characters with them, and thus intelligibly correspond with each other in writing, though ignorant of the language spoken in their several countries. Our European arithmetical figures are significant marks, precisely of the same nature with the Chinese characters. Thus far nothing has appeared which resembles our letters, or which can be called writing, in the sense now given to that term. What we have hitherto seen were all direct signs for things, and made no use of the medium of sound or words; either signs by representation, as the Mexican pictures; or signs by analogy, as the Egyptian hieroglyphics; or signs by institution, as the Peruvian knots, the Chinese characters, and the Arabian cyphers. At length, in different nations, men became sensible of the imperfection, the ambiguity, and the tediousness of each of these methods of communication with one another, and began to consider the advantage resulting from employing signs, which should stand not directly for things, but for the words which they used in speech for naming these things; and they also considered, that though the number of words in every language be very great, yet the number of articulate sounds, used in composing these words, is comparatively small. Hence they were led to invent signs, not for each word by itself, but for each of those simple sounds that are employed in forming words; and they observed, that by joining together a few of those signs, it would be practicable to express, in writing, the whole combination of sounds which our words require.

The first step in this new progress was the invention of an alphabet of syllables, which probably preceded the invention of an alphabet of letters, among some of the ancient nations; and which is said to be retained, to this day, in Ethiopia, and some countries of India. By fixing upon a particular mark or character for every syllable in the language, the number of characters, necessary to be used in writing, was reduced within a much smaller compass than the number of words in the language. Still, however, the number of characters was great; and must have continued to render both reading and writing very laborious arts. At last some happy genius arose; and tracing the sounds made by the human voice to their most simple elements, reduced them to a very few vowels and consonants; and, by affixing to each of these the signs which we now call letters, taught men how, by their combinations, to put into writing all the different words, or combinations of sound, which they employed in speech. By being reduced to this simplicity, the art of writing was brought to its highest state of perfection, and in this state, we now enjoy it in all the countries of Europe.

To whom we are indebted for this admirable and useful discovery does not appear. There seems reason to conclude, from the books which Moses has written, that, among the Jews, and probably among the Egyptians, letters had been invented prior to his age. The universal tradition among the ancients is, that they were first imported into Greece by Cadmus the Phœnician, who, according to the common system of chronology, was contemporary with Joshua; but according to sir Isaac Newton's system, contemporary with king David. As the Phœnicians are not known to have been the inventors of any art or science, though, by means of their extensive commerce, they propagated the discoveries made by other nations, the most probable and natural account of the origin of alphabetical characters is, that they took rise in Egypt, the first civilized kingdom of which we have any authentic accounts, and the great source of art and polity

among the ancients. In that country, the favourite study of hieroglyphical characters had directed much attention to the art of writing. Their hieroglyphics are known to have been intermixed with abbreviated symbols, and arbitrary marks; whence, at last, they caught the idea of contriving marks, not for things merely, but for sounds. Accordingly, Plato (in Phædro) expressly attributes the invention of letters to Theuth or Thoth, the Egyptian, who is supposed to have been the Hermes, or Mercury, of the Greeks. Cadmus himself, though he passed from Phœnicia to Greece, as several of the ancients have affirmed, was originally of Thebes in Egypt. Most probably Moses carried with him the Egyptian letters into the land of Canaan; and there, being adopted by the Phœnicians who inhabited that part of the country, they were transmitted into Greece.

It is curious to observe, that the letters which we use at this day, can be traced back to the alphabet of Cadmus. The Roman alphabet, which obtains with us and most of the European nations, is plainly formed on the Greek, with a few variations. And all learned men observe, that the Greek characters, especially according to the manner in which they are formed in the oldest inscriptions, have a remarkable conformity with the Hebrew or Samaritan characters, which, it is agreed, are the same with the Phœnician, or the alphabet of Cadmus. If the Greek characters are inverted from left to right, according to the Phœnician and Hebrew manner of writing, they will appear to be nearly the same. Beside the conformity of figure, the names or denominations of the letters, alpha, beta, gamma, &c. and the order in which they are arranged, in all the several alphabets, Phœnician, Hebrew, Greek, and Roman, agree so much, as to amount to a demonstration that they were all originally derived from the same source. The letters were, at first, written from the right-hand to the left; and this manner of writing obtained among the Assyrians, Phœnicians, Arabians, and Hebrews: and from some very old inscriptions, it appears to have obtained also among the Greeks. Afterwards the Greeks adopted the method of writing their lines alternately from the right to the left, and from the left to the right, called *boustrophedon*. At length, however, the motion from the left-hand to the right being found more natural and commodious, the practice of writing, in this direction, prevailed throughout all the countries of Europe. See more on this subject under ALPHABET, CHARACTERS, and LETTERS.

Writing was long a kind of engraving. Pillars, and tables of stone, were first employed, and afterwards, plates of the softer metals, such as lead: but as writing became more common, lighter and more portable substances were employed. The leaves, and the bark of certain trees, were used in some countries; and in others, tablets of wood, covered with a thin coat of soft wax, on which the impression was made with a stylus of iron. See BOOK, BARK, and STYLE.

In later times, the hides of animals, properly prepared and polished into parchment, were the most common materials: our present method of writing on paper is an invention of no greater antiquity than the fourteenth century.

The advantages of writing above SPEECH (which see) are, that writing is both a more extensive and a more permanent method of communication: nevertheless, spoken language has a great superiority over written language, in point of energy or force. See Warburton, *ubi supra*. Blair's Lectures on Rhetoric, &c. vol. i. lect. 7.

An ingenious and learned writer has lately discussed the subject of this article in a very elaborate manner. He observes, that there is a difference, deserving particular attention in the inquiry, concerning the origin and progress of writing, between the imitative characters and symbolic or arbitrary marks. The former derive their origin from that imitative faculty, which is so conspicuous in the human species; the latter are founded in necessity or convenience, and become significant by compact: the one comprehends symbols and marks for sounds, significant of ideas; and the other have an immediate reference to sensible objects which present themselves to sight, and are applicable to hieroglyphical representations. Accordingly all representations, marks, or characters, which were ever used by any nation or people, must have been either imitative or symbolic.

This writer controverts the opinion of M. Fourmont, bishop Warburton, and M. Gebelin, who have endeavoured to shew, that alphabets were originally formed of hieroglyphical characters; alleging that the letters of an alphabet were essentially different from the characteristic marks deduced from hieroglyphics, which are marks for things and ideas, like the ancient and modern characters of the Chinese; whereas the former are only marks for sounds; and that, though there be a sufficient resemblance between the Mexican picture-writing, the Egyptian hieroglyphics, and the Chinese characters, yet these are foreign to alphabetic letters, and, in reality, do not bear the least relation to them. The hieroglyphic characters of the Chinese are, it is said, in their nature imitative, and do not combine into words, like arbitrary marks for sounds or letters, which are very few, and of a symbolic nature.

Letters, it is maintained, do not derive their powers from their forms, but originally their forms entirely depended on the fancy or will of those who made them.

Many learned men have supposed, that the alphabet was of divine origin; and several writers have asserted, that letters were first communicated to Moses by God himself; whilst others have contended, that the Decalogue was the first alphabetic writing. But if this art had been a new discovery in the time of Moses, he would probably have commemorated it; nor is there any reason to suppose, that God was the immediate revealer of the art, for Moses could never have omitted to have recorded the history of so important a circumstance, as the memory of it would have been one of the strongest barriers against idolatry.

It appears, however, that the art of writing is of great antiquity, and that the ancients, who ascribed the invention of it to the gods, had very imperfect ideas of its true origin. When it is considered that letters must have been the produce of a certain degree of civilization among mankind, the inquirers into their original have been naturally led to seek it in the history of those nations that appear to have been first civilized. Accordingly, many authors have decided in favour of the Egyptians. See LETTERS.

Others have vindicated the claim of the Phœnicians to the invention of letters; urging the testimony of Sanchoniatho, the most ancient and also the most celebrated Phœnician historian, corroborated by Pliny, Curtius, Lucan, Eusebius, &c. as well as their very early and high degree of civilization. The Chaldeans have also had several learned advocates, who have attributed the invention of letters to the patriarch Abraham: and sir Isaac

Newton, in particular, admits, that letters were known in the Abrahamic line for some centuries before Moses.

It is needless to mention the claims of the Tuscans, Indians, and Arabians. Mr. Aistle, *ubi infra*, declares in favour of the Phœnicians; and observes, that as the Chaldeans, Syrians, Phœnicians, and Egyptians, all bordered upon each other, and as the Phœnicians were the greatest as well as the most ancient commercial nation, it is very probable that they communicated letters to the Egyptians; the ports of Tyre and Sidon, and those of the Egyptians, being not far distant from each other. This author adds, that before the time when Mizraim went into Egypt, in the year before Christ 2188, and 160 years after the flood, Taaut, his son, had invented letters in Phœnicia; and if this invention took place ten years before the migration of his father into Egypt, as Mr. Jackson supposes, we can trace letters as far back as the year 2178 before Christ, and 150 after the deluge recorded by Moses: and beyond this period, the written annals of mankind, which have been hitherto transmitted to us, will not enable us to trace the knowledge of them, though this want of materials is no proof that letters were not known until a century and a half after the Deluge.

An opinion seems to be gaining credit among the learned, that arts and letters took their rise in the northern parts of Asia, and that they were cultivated in those parts, long before they were practised in Phœnicia or Egypt. Some travelled southwards, others staid behind; and those who afterwards emigrated from the East were generally called Scythians, and sometimes Huns, who overspread the northern parts of Europe. Many settlements were made in Germany long before the Christian era.

It has been asserted by many writers, that all alphabets are derived from one; but Mr. Aistle maintains, that there are various alphabets used in different parts of Asia, which differ from the Phœnician, ancient Hebrew, or Samaritan, in name, number, figure, order, and power. In several of these alphabets, there are marks for sounds peculiar to the language of the East, which are not necessary to be employed in the notation of the languages of Europe.

The following alphabets, says this learned writer, seem to be immediately derived from the Phœnician; *viz.* the ancient Hebrew, or Samaritan; the Chaldaic; the Bactrian, or that of the colony of Phœnicians or Canaanites, who are said to have fled from Joshua, and to have settled themselves, in the most early ages, in that part of Spain now called Andalusia and Grenada; the Punic, Carthaginian, or Sicilian; the Pelasgian Greek, and its derivatives, which are written in the Eastern manner, from right to left; and the Ionic Greek, written from left to right. This last-mentioned branch from the Pelasgic stock is the source from whence not only most of the alphabets of Europe are derived, but also of many others which have been adopted in different parts of Asia and Africa. From the Ionic Greek are derived the Arcadian, the Latin or Roman, the ancient Gaulish, the ancient Spanish, the ancient Gothic, the Coptic, the Russian, the Illyrian or Sclavonian, the Bulgarian, and the Armenian: the Runic is immediately derived from the Gothic.

The alphabets derived from the Roman are, the Lombardic, the Visigothic, the Saxon, the Gallican, the Franco-Gallic or Merovingian, the German, the Caroline, the Capetian, and the Modern Gothic. The first relates to the MSS. of Italy; the second, to those of Spain; the third, to the MSS. of Great Britain; the fourth and fifth,

to those of France; the sixth, to Germany; the seventh, eighth, and ninth, to all the countries of Europe where Latin is read. The six former alphabets are before the age of Charlemagne; the three latter follow it. The characters of these are more distinguished by their names than by their forms, which indicate that they are all of Roman extraction. The Lombardic, introduced into Italy by the Lombards in 569, was used by the popes in their bulls, and sometimes called Roman in the eleventh century: it ceased in the thirteenth century. The Visigothic, or Spanish Gothic, was introduced into Spain by the Goths or Visigoths; it was abolished in a provincial synod, held at Leon in 1091, when the Latin letters were established for all public instruments; though these characters were occasionally used in private transactions for upwards of three centuries afterwards. Saxon writing admits of various distinctions, *viz.* the Anglo-Saxon, Britanno-Saxon, and Dano-Saxon. The Gauls, on being subdued by the Romans, adopted their mode of writing; and by additions of their own, gave rise to the Gallican or Roman Gallic. The Franks, a people of Germany, having conquered part of Gaul, introduced their characters called Franco-Gallic, or Merovingian, because this kind of writing was practised under the kings of the Merovingian race. It took place about the close of the sixth century, and prevailed till the beginning of the ninth. The Caroline was derived from the improvement of Charlemagne; this declined in the twelfth century, and totally disappeared in the thirteenth, when it was succeeded in Germany by the Modern Gothic. The Caroline writing was restored by Hugh Capet about the year 987, and called Capetian: it was much practised till about the middle of the twelfth century; but in the thirteenth it degenerated into the Modern Gothic. The Capetian writing was used in England and in Germany, as well as France, during the above-mentioned period. The Modern Gothic, which spread itself over Europe in the twelfth and thirteenth centuries, is improperly so called; because it does not derive its origin from the writing anciently used by the Goths and Visigoths in Italy and Spain, but it is the most barbarous kind of writing: it took its rise in the decline of the arts among the lazy schoolmen, who had the worst taste; it is nothing more than the Latin writing degenerated. It began in the twelfth century, and was generally used (especially by monks and schoolmen) in all parts of Europe, till the restoration of the arts in the fifteenth century, and longer in Germany and the northern nations. Our statute-books are still printed in Gothic letters.

The learned are not agreed with respect to the origin of what is called *national* writing. Some will have it, that the Roman manner prevailed throughout the West, until the irruption of the barbarous nations of the North, in the fifth and sixth centuries: the Goths, they say, first introduced their mode of writing into Italy, instead of the Roman manner; the Visigoths did the like in Spain; the Franks in Gaul; the Saxons in England; and the Lombards in Italy.

According to others, the Romans were in possession of various forms of writing; but it is supposed, that the barbarous nations introduced some of their own letters in the writings composed of capitals and small letters; that the running-hand, peculiar to each nation, was used in grants and contracts, and found admittance likewise in manuscripts after the middle of the seventh century.

Mr. Aftle, however, is of opinion, that the different

modes of writing in Italy, Spain, France, England, and Germany, were derived from the Roman alone.

While Rome continued the centre of all the provinces of the empire, her manner of writing generally prevailed in each; but the empire being dismembered, and all the western provinces disunited, a change was produced; the conquerors disfigured the Roman writing, and by their false taste and ignorance, distinguished their writing from that of their neighbours: the genius and disposition of the different people having no small share in producing this diversity.

This notion greatly assists in discovering the age of manuscripts; for if a writing is Merovingian, it cannot be subsequent to the ninth, nor prior to the fifth century; if another is Lombardic, it must be posterior to the middle of the sixth, and anterior to the thirteenth; if Saxon, it cannot be earlier than the seventh, nor later than about the middle of the twelfth.

With regard to the forms of letters, many authors are of opinion that they are derived from the positions of the organs of speech in their pronunciation. Accordingly, M. Van Helmont hath taken great pains to prove, that the Chaldaic characters are the genuine alphabet of nature, because, he says, no letter can be rightly founded, without disposing the organs of speech into an uniform position with the figure of each letter.

Mr. Nelme published a work, in which he endeavours to shew that all elementary characters or letters derive their form from the line and the circle. Mr. Gebelin deduces them from hieroglyphic representations, and he hath given several delineations of human figures, trees, &c. in confirmation of his hypothesis. Mr. Aftle observes, that as letters are only marks for sounds, their forms entirely depended upon the taste, fancy, will, or caprice, of those who first formed them. In this point of view, they may be considered as arbitrary marks, or secret cyphers, which, by being made known and adopted, would become of general use, wherever they were received by agreement. For the number and forms of the letters of various alphabets, illustrated by figures, we must refer to Mr. Aftle's account, *ubi infra*.

After the most diligent inquiry, it doth not appear, says Mr. Aftle, that the Britons had the use of letters before their intercourse with the Romans: and though, from the coming of Julius Cæsar till the time when the Romans left the island in the year 427, the Roman letters were familiar to the eyes of the inhabitants, he is of opinion, that writing was very little practised by the Britons till after the coming of St. Augustine, about the year 596.

The writing which prevailed in England from this time to the middle of the eleventh century, is generally termed Saxon, and may be divided into five kinds; *viz.* the Roman Saxon, which is very similar to the Roman, and prevailed in England from the coming of St. Augustine till the eighth century; the set Saxon, which took place toward the middle of the eighth century, continued till about the middle of the ninth, and was not entirely disused till the beginning of the tenth century; the running-hand Saxon, which came into use towards the latter end of the ninth century, when learning was diffused in England under the auspices of king Alfred, in whose reign many books were written in this island, in a more expeditious manner than formerly; the mixed Saxon, occurring in the ninth, tenth, and in the beginning of the eleventh centuries, in many MSS., which were written in England in characters partly Roman, partly Lombardic, and partly Saxon; and the elegant

elegant Saxon, which took place in England early in the tenth century, lasted till the Norman Conquest, but was not entirely diffused till the middle of the twelfth, and is more beautiful than the writing in France, Italy, and Germany, during the same period.

The writing introduced into England by William I. is usually called Norman, and is composed of letters nearly Lombardic, which were generally used in grants, charters, public instruments, and law proceedings, with very little variation, from the Norman Conquest till the reign of king Edward III.

About the reign of king Richard II. variations took place in writing records and law proceedings; the charters from the reign of king Richard II. to that of king Henry VIII. were composed partly of characters called set chancery and common chancery, and some of the letters called court-hand; which three different species of writing are derived partly from the Norman and partly from the modern Gothic. The modern Gothic began to take place in England in the twelfth century; the old English about the middle of the fourteenth century; and set chancery and common chancery in the decline of the same century, and are still used in the enrolments of letters patent, charters, &c. and in exemplifications of recoveries: the court-hand was contrived by the English lawyers, and took its rise about the middle of the sixteenth century, and continued till the beginning of the late reign, when it was abolished by law. The court-hand characters were nothing more than the Norman characters very much corrupted and deformed.

In the sixteenth century, the English lawyers engrossed their conveyances and legal instruments in characters called secretary, which are still in use.

The French call their writing by the names of the different races of their kings, in whose time they were written: these were, the Merovingian, the Carolingian, the Capetian, the Valésian, and the Bourbonian.

The writing called Merovingian began in France soon after the time of Merovæus, son of Pharamond; who was made king A.D. 460: this race ends with Childeric, who died in 752. The Caroline race properly began with Pepin, who was made king of France upon the death of Childeric. This prince was succeeded by Charlemagne, A.D. 814, whose line in France ended with Lewis V. A.D. 987. The Capetian race began with Hugh Capet, who succeeded Lewis V., and ended with Charles IV. A.D. 1327. The Valésian race began with Philip IV. the successor of Charles IV., and ended with Henry III. the last of this line, who was slain in 1589. The Bourbonian line began with Henry IV. A.D. 1589, whose descendants now fill the throne of France.

The MSS. written in the northern parts of Scotland and in Ireland are in characters similar to the Saxon. The learned and ingenious colonel Vallancey thinks, indeed, that the Iberians, who migrated from the borders of the Euxine and Caspian seas, and settled in Spain, learned letters and arts from the Phœnicians: that a colony of the ancient Spaniards, by the name of Scots or Scythians, settled in Ireland about a thousand, or perhaps six hundred years before Christ, and that they brought elementary characters with them into Ireland. He observes, that the Irish alphabet differs from that of all other nations, in name, order, number, and power, and supposes, that they might have received their alphabet from the Carthaginians, who also settled a colony in Ireland about six hundred years before Christ; and adds, that this opinion is the more to be credited, as the Irish language appears to have a radical identity with the Punic.

VOL. XXXVIII.

In order to discover what real pretensions the Irish have to the early use of letters, for which they eagerly contend, Mr. Astle has examined their stone monuments, their coins, and their MSS., and appealed to the historians of that country. The letters upon the most ancient of their monuments are apparently of Roman and Roman-British original; and none of these inscribed monuments are so ancient as to prove that the Irish were possessed of letters before the Romans had intercourse with the Britons; though they prove that they had letters before the arrival of St. Patrick in that kingdom, which, Mr. Whitaker, with great probability of truth, says, were waisted over from the Caledonians, who used the Roman letters. Sir James Ware says, that the Irish alphabet was borrowed from the British, and that the Saxon characters were nearly the same as the Irish; and adds, that Mr. Camden inclined to this opinion.

Moreover, there are no Irish coins, inscribed with letters, till long after the twelfth century: except coins struck by some of our Saxon kings, who made incursions into that country, and struck money there in the Saxon manner.

The oldest Irish MS. which has been discovered is the Psalter of Cashel, written in the latter end of the tenth century.

The testimony of approved historians is likewise unfavourable to the ancient literature of Ireland. Mr. Innes, in his Essay on the Antiquities of Scotland and Ireland, and Mr. James Macpherfon, in the third edition of his Introduction to the History of Great Britain and Ireland, maintain, that Ireland was first peopled from Britain; and that the manners of the old Irish were inconsistent with the knowledge of letters.

It seems probable, that the interior parts of Europe were immediately peopled from the northern parts of Asia, and the maritime parts from Phœnicia, and the southern and western parts of that quarter of the globe. If this be the case, it is not surprising that some Eastern customs prevailed in Great Britain and Ireland, and that many Celtic words are still preserved both in the Irish and in the Welsh languages.

The Norman characters, it is observed, were generally used in England from the coming of William I., and the Saxon characters were entirely diffused in the very beginning of the twelfth century; but the Irish and Scots preserved the ancient forms of their characters till the end of the sixteenth century.

The Gaëlic or Erse language, used in the Highlands of Scotland, and the Ibero-Gaëlic, are nearly the same, and their letters are similar to each other, as Mr. Astle has shewn by various specimens. The curious will find much information on the subject of this article in Astle's Origin and Progress of Writing, 4to. 1784.

J. Ravenau has a treatise, intitled "Des Inscriptions en Faux," in which he shews how to revive and restore old writings almost effaced, by means of galls ground in white wine and distilled, and thus rubbed over the writings.

To write without blacking the fingers: prepare the paper with a fine powder, made of three parts of calcined copersas, two of galls, and one of gum arabic; those being fresh mixed, rub them with a hare's foot into the pores of the paper, and then write with fair water, and the black letters will immediately appear.

To make new writing appear old, moisten it with oil of tartar *per deliquium*, more or less diluted with water, as you desire the ink to appear more or less decayed.

We may write without ink or its materials; for this purpose, take a fine powder of calcined hartshorn, of clean tobacco-pipes, or rather of mutton-bones burnt to a perfect

whiteness, and rub it upon the paper, and then write with a silver bodkin, or the like. Boyle's Works abr. vol. i. p. 114, 115. See **INK**.

The discharging of ink out of parchment, paper, &c. is commonly done by aqua fortis diluted sufficiently with water, that it may not destroy the paper. The like may be done with oil, or spirit of vitriol diluted. The juice of lemons, or strong vinegar, will take ink out of linen more safely, as the mineral acids are apt to destroy the linen, unless great care be used in diluting them.

We may write on iron with corrosive sublimate wetted with common water: for this purpose, the parts of metal we would preserve untouched should be covered with wax, and that taken off in the proper places to make way for the corroding substance. Boyle, *ib.* p. 528.

The like may be practised by means of aqua fortis.

Mr. Boyle mentions a method he had of copying a whole page of writing at once. But we do not find his description of it any where. *Ib.* p. 136.

A machine has been lately invented and constructed by Messrs. Watt and Co. of Birmingham; by means of which letters and other writings may be copied. For an account of the structure and use of this machine, we must refer to the directions for copying with it, furnished by the inventors; observing, however, that the date, at which a writing will yield a copy, is extremely uncertain, from the weather, as it is more or less drying, and from the state of the ink. In general the purpose will be answered to the end of twenty-four hours, and sometimes of three or four days; but it is most advisable to copy letters as soon after they are written as may prove convenient. See **COPYING**.

Mr. Boyle informs us of a method of imitating writing on copper-plates. The copy to be engraved is to be wrote with a peculiar kind of ink, and the copper-plate being moderately warmed is rubbed over with a white varnish, and suffered to cool; then the paper being gently moistened, that it may readily communicate its ink, the writing is applied to the prepared surface of the plate, and passed through a rolling-press; by which means, the ink adhering to the varnish leaves the letters very conspicuous. And hence it is easy with a needle to trace the strokes through the varnish upon the plate, which being afterwards cleaned, the letters are finished with the graver, and the work printed off in a rolling-press, as common cuts.

Mr. Boyle does not mention what the varnish or ink, used by the artificer from whom he received this method, was; but he tells us, that he himself used the purer sort of virgin wax for a varnish; and for his ink he took fine Frankfort black, carefully ground with water, till it obtained the consistence of common ink; but no gum was added, lest it should hinder the ink from coming off. He also observes, that written characters may be taken off without the help of a press, by laying the moistened paper smooth upon the varnished copper, and rubbing it on hard with a convex piece of glass. See **SYMPATHETIC INK**.

In law, we say, deeds, conveyances, &c. are to be in writing. A will may either be in writing, or by word of mouth.

We also say, *written law, lex scripta*, in opposition to common law, which is called *lex non scripta*. We have also *written and unwritten traditions, &c.*

Authentic writings of any contract, sealed and delivered, make the evidences thereof.

La Vayer has a curious dissertation on the proof of facts by comparison of hand-writings, in which he endeavours to shew this method of proof to be very suspicious and fallacious.

WRITZEN, in *Geography*, a town of the Middle Mark of Brandenburg, on a branch of the Oder; 18 miles N.W. of Custrin.

WRONG, in a *Logical Sense*. See **ERROR, FALSEHOOD, and TRUTH.**

WRONG, in a *Legal Sense*, *injury, tort*. See **INJURY, and TORT.**

Wrongs are divisible into two sorts, *viz. private and public*. The former are an infringement or privation of the private or civil rights belonging to individuals, considered as such; and are frequently termed *civil injuries*. The latter are a breach and violation of public rights and duties, which affect the whole community, considered as such; and are distinguished by the harsher appellation of *crimes and misdemeanours*.

WRONG, Executor of his own. See **EXECUTOR de son Tort.**

WRONG-Lands, in our *Old Writers*, seem to denote trees that will never prove timber; such as wrong the ground they grow in.

WRONGS, in *Agriculture*, a term applied to the crooked arms or large boughs of trees, when the fagot-wood is cut off from them.

WROTHAM, in *Geography*, a market-town in the upper half hundred of the same name, in the lathe of Aylesford, and county of Kent, England, is situated near the base of some chalk-hills, at the distance of 10 miles W.N.W. from Maidstone, and 24 miles S.E. by E. from London. The manor was granted by king Ethelstan, in the year 964, to the priory of Christ-church, Canterbury. On the division of the possessions of the monks by Lanfranc, it was allotted to the archbishops of Canterbury, who had a palace and frequently resided here, till the time of archbishop Islip, who pulled down the buildings for the sake of the materials, which he applied to the completion of the palace at Maidstone, which his predecessor, John Ufford, had begun. Archbishop Cranmer resigned the manor to Henry VIII., and it was granted by Edward VI. to sir John Mason, who disposed of it to the Byngs, ancestors of the lords Torrington, of whom it was purchased by William James, esq. of Ightham, whose descendants still possess it. Wrotham church, the only public edifice in the town, is a spacious well-built structure, and consists of a nave, aisles, chancel, and transept, with an embattled tower at the west end; the chancel is light and elegant. The sepulchral memorials are numerous; among which are several curious brasses, recording the family of Peckham, who were resident in this parish during several centuries. The Rayner family, who resided at Wrotham-Place the whole of the 17th century, have also monuments here. The rectory is esteemed one of the best livings in Kent. Of the ancient archiepiscopal palace little now remains but a gateway, and a substantial stone building which formed part of the offices. The population return of the year 1811 states the town to contain 107 houses, and 613 inhabitants. Here is an annual fair, and a weekly market on Tuesday. The parish is very extensive, comprehending the villages of Hale, Nepicar, Plaxted, Winfield, and Roughway. In a park within the limits of the parish is a capital mansion, once the seat of sir Harry

Harry Vane, who on the restoration of Charles II. suffered death for the part he took against Charles I. This estate, on the death of lord viscount Vane in 1789, became the property of David Papillion, esq.: it is now occupied by the earl of Delawar.—*Beauties of England and Wales*, vol. viii. Kent, by E. W. Brayley, 1807.

WROTZKO, a town of Prussia, in the palatinate of Culm; 12 miles S.W. of Strasburg.

WROUGHT, in *Ship-Building*, a term applied to any piece of timber, &c. when it is trimmed and fitted for its situation.

WROXETER, in *Geography*, a village of England, in the county of Salop, at the union of the Torn and the Severn, by Antoninus called "Uriconium," by Ptolemy "Viriconium," by the Welsh and Britons "Caer Vruach," and by the Saxons "Wrekenceaster." It was the chief city of the Cornavii, and founded by the Romans, when they fortified the bank of the Severn where fordable. It was encompassed by a rampart and ditch; the walls were three yards thick, and were three miles in circumference. After suffering much in the Saxon wars, it was quite ruined by the Danish, and is now but a small place. Many Roman coins and other antiquities have been found here; 5 miles S.E. of Shrewsbury, and 155 N.W. of London.

WRUNG-HEADS, a former name given to the bilge of a ship, &c. or that part near the floor-heads, which, when a ship lies aground, bears the greatest strain.

WRY-NECK, (*Caput obliquum, cervix obliqua, torticollis*,) denotes that deformity of the human body, in which the neck is bent laterally, generally inclining at the same time somewhat forwards, so that the head is also drawn to one side and forwards, being indeed frequently quite approximated to the shoulder. For the most part, the neck is in this case altogether irregularly formed: on the side towards which the head inclines, it seems exceedingly plump, the strong shortened muscles being bulky, and affected with considerable spasm; while, on the other hand, the opposite side, where the neck is convex, exhibits no such strong rigid muscles, or at all events so little of this appearance, that, notwithstanding its convex form, it seems obviously less fleshy. When the disease has continued a long while, and attained a serious degree, its effects extend also to the head itself. On that side where the irregular action of the muscles is strongest, and where consequently the head is most drawn downwards, the half of the face is usually more or less contracted, and weaker than the opposite half, the zygomaticus major, the buccinator, the masseter, and other muscles, being considerably less prominent. This disfigurement of the countenance has a very unpleasant appearance, and plainly indicates the distorted position into which the head is drawn. The patients are also incapable of turning their heads properly, or of directing their faces upwards; and if these functions can be executed in a very imperfect way, it is not without a good deal of effort, which in general the patients prefer avoiding. Hence they mostly choose to remain in their distorted posture, and instead of trying to turn their heads with the muscles of the neck alone, they prefer accomplishing this object rather by turning the whole body. Hence an opportunity is given for the evil to increase in a very rapid and afflicting degree. According to the observations of Richter and Bernstein, the face is commonly turned towards the opposite side, and only now and then towards that to which the head inclines. (*Anfangsgr. der Wundarzneykunst* 4ter. Band, 2te. Auflage, f. 256. *Practischen Handbuche für Wundärzte*, &c. Neue Auflage, 3ter. Theil, f. 215.) Professor Jörg of Leipzig does not

exactly coincide with these surgeons on this particular point; but we think that the difference is merely in terms, and not in the thing itself, Richter meaning that the face is turned towards the sound side, not that it is drawn away, and made more distant from the shoulder to which the whole neck and head incline. Professor Jörg takes a review of the action and insertions of the sterno-cleido-mastoideus muscle, which proceeds down the neck from the mastoid process, and splits into two portions; one of which is inserted into the external and anterior part of the clavicle, the other into the upper and outer surface of the sternum. The clavicular portion of this muscle must necessarily tend to draw the head towards the clavicle, which is the fixed point, while the sternal portion will pull it towards the breast; but both acting together, will draw it in a diagonal line. At the same time that they have the effect of inclining the head forwards and to one side, they impart to the neck the same direction, and even slightly turn it, so that the nose is no longer situated in a straight line directly over the sternum, but is placed to one side of such a line. When, for example, says professor Jörg, the right sterno-cleido-mastoideus is too short, and is therefore the cause of the wry-neck, it will pull the head towards the right side, and also forwards, in such a manner that the nose is moved to the left of a line drawn upwards from the sternum, and the neck itself is at the same time slightly turned. But when this is the case, the whole face must obviously be somewhat turned towards the left side, and drawn a little way downwards and forwards. When, however, the whole head is drawn forwards, laterally, (in this case to the right,) and at the same time downwards, consequently the face forwards, laterally, (in this case to the left,) and downwards, it cannot be said that the face is moved in a different direction from that of the rest of the head. Although the face is turned in a different direction, still it is not inclined towards the opposite side; for, says professor Jörg, if this were so, the neck must be much more turned than actually happens. Hence, he thinks, that a case has really never existed, where the face and head have been inclined in different directions.

With respect to the causes of this infirmity, they are, according to several writers, very numerous, and it is not to be denied that they may be of different kinds. Yet, says Jörg, "I have never seen the complaint originate in the bones: the muscles were always the parts first concerned. According to my observations, the sterno-cleido-mastoideus must be looked upon as being the chief original cause of this deformity, which I have never seen unattended with the particular and manifest influence of that muscle. When also several other muscles gradually participate in the disorder, the sterno-cleido-mastoideus is usually the first affected. While it is more disposed to an irregular action than any other muscle of the neck, its greater strength makes it in some measure govern the rest." As children, both in the erect and horizontal postures, frequently keep their necks unevenly, and more to one side than the other, professor Jörg conceives that this will account for one sterno-cleido-mastoideus readily becoming shorter than its fellow; the equilibrium ceases, and a wry-neck is immediately produced. Young children often contract a habit of lying in bed constantly upon the same side, whereby the muscles of the neck become gradually habituated to an irregular kind of tension, which by degrees breaks the antagonizing power between the opposite sets of muscles. The same thing happens, when children are constantly carried with their head upon one and the same side of their nurse. But this irregularity in the muscles in question is also frequently

quently congenital, and then we need not specify any occasional causes. The evil, though it exists at the time of birth only in a trivial degree, afterwards quickly increases, and soon becomes serious. The regular equilibrium between the sterno-cleido-mastoidei may likewise be destroyed, when one of them is wounded, or completely cut through; when it remains preternaturally weak, in consequence of having been the seat of abscesses, and previous ulceration; or when, from any cause whatsoever, its action is rendered either too feeble or too powerful.

In one patient cured by professor Jörg, it is alleged that the inner portion of the left sterno-cleido-mastoideus was inserted into the middle and right side of the sternum, in the same place as the inner portion of the muscle of this name on the right; and the above author conceived, that this preternatural attachment was probably the cause of the inclination of the head to the right side.

Professor Jörg does not give much credit to the opinion, that the wry-neck is frequently brought on by a contraction of the skin of the neck and of the platysma myoides; the first of these parts being very yielding, and the second very thin and elastic. But, he thinks, that when these parts, or any other muscles of the neck, are shortened and spasmodically contracted, it is generally as a consequence of the affection of the sterno-cleido-mastoideus, which is the part originally disordered.

The same writer will not deny also, that the malformation of the bones may be the first cause of this infirmity. If, says he, the dorsal and lumbar vertebræ are liable to curvature, why should the cervical ones not be so, and thereby destroy the equilibrium between the muscles of the neck? Yet, he thinks, the cause of the disorder must lie much more rarely in the bones than the muscles, since he has never seen one instance of it. He admits also, that there can be no doubt that the bones sooner or later share in the effects of the disease; that they become bent to one side, and even cemented together by ankylosis.

As in every other disorder, the practitioner must endeavour to find out the original cause of the complaint; and, therefore, the question arises, how can it be known whether the muscles and the integuments, or the bones, are the first cause of the deformity? The cause may be ascribed to the muscles, when there is obviously something wrong about them; when they are hard and contracted on one side, and soft and little prominent on the other; and when those which are shrunk and shortened become still harder and more painful, on putting the head in a straight position, to the doing of which they also make more or less resistance. We may be more certain of the thing, when no disease of the bones in any part of the body, and no causes of such complaint, can be detected; for when the bones are about to soften, or are already softened, the latter affection must be preceded by certain occasional causes, and accompanied with the usual symptoms. The discovery of these, according to professor Jörg, is not difficult to the practitioner, at least not impossible. The disorder, on the other hand, may be referred to the bones, when no particular defect about the muscles is apparent, when they are no where remarkably hard and contracted, and when the case is attended with symptoms and vestiges of a partial or general softening of the bones. When this is the case, the muscles are usually much less altered than when they constitute the original cause of the deformity; and the head can be more easily raised, turned, and moved about.

Another question is, what degree has the disorder already attained, and have the bones materially participated in the affection or not? Perhaps the cervical vertebræ are

ankylosed? Although it may at first seem easy to answer these questions, yet it is not always so easy. The prognosis and treatment, however, are to be regulated by the decision; and we can never speak satisfactorily of the case, unless we have inquired into the whole of its progress.

When the bones are affected, that is to say, when in consequence of the wrong posture of the neck a change has taken place in their form; when they, as is most usual, on the side towards which the head is inclined, are lower than on the other; or when their processes are diminished or absorbed; the practitioner can frequently feel and see that the defect lies in the texture of the bones. The depressions thus produced may sometimes be plainly seen, or, at all events, can be felt with the finger. When the head and neck are put into the right position, these depressions become still more obvious, as well as the alteration of the spinous processes. In order to derive from such examination any precise knowledge, we must indeed be well acquainted with the anatomy of the neck. Professor Jörg then gives us some directions how to move the head and neck, and how to place our fingers in trying to ascertain whether the cervical vertebræ are ankylosed. We pass these over, because we place very little confidence in their accuracy or utility.

The professor next notices the influence which the deformity has over the whole organization of the body. An imperfection in the formation of the head is the first and principal effect derived from the infirmity. In cases of wry-neck, he has never seen the face and head altogether well constructed. The half of the face which was nearest to the contracted sterno-cleido-mastoideus was always smaller, and less prominent, than the other. Frequently the lower jaw, the zygoma, and the eye, were more sunk on this side than the other, and hence the countenance presented a very distorted emaciated appearance. The foregoing author has also constantly found the raising of the head, and other motions of this part, materially prevented. The patients always stoop to one side in a most awkward kind of posture. None of them can turn their heads well. Whenever they want to look laterally, they are obliged to turn their whole bodies. Hence many of them become disqualified for certain occupations, and even if they are capable of work, they labour with more difficulty than other persons. The preternatural dragging downward of the head, and the curvature of the cervical vertebræ, one would think (says professor Jörg) would have a bad effect on the functions of the brain and spinal marrow. He has, however, never seen this happen; but on the contrary, in the worst forms of the complaint, he has not found the brain at all affected. Still he does not venture to conclude that things are always so. Our limits oblige us to pass over some other remarks on the preceding topic, in order to begin the consideration of the method of treatment.

We find then that the wry-neck mostly arises from an affection of the muscles, and especially from irregular action in the sterno-cleido-mastoidei, the equilibrium between which is destroyed: hence the treatment is generally directed against the muscles, particularly those above-mentioned. It is seldom that it is necessary to do any thing for the bones. For this reason, the prognosis is generally favourable, and this the more so the younger the patient is, and the more yielding the contracted sterno-cleido-mastoideus happens to be found. Indeed, when the patient is farther advanced in life, and not more than twenty-five or thirty years of age, we should not totally despair of being able to render assistance, if no ankylosis exist, and not too much deformity of the cervical vertebræ. What kind of a prog-

rosis can be made, when the bones are originally concerned in the production of a wry-neck, must depend upon the nature and degree of the morbid affection of those parts.

In the treatment of a wry-neck, we must endeavour to soften and relax the contracted muscles, and strengthen those which are stretched and tense. The first indication, Jörg thinks, may be fulfilled by the use of oily emollient liniments two or three times a day; the second by the employment of spirituous stimulating embrocations. When common applications of the last kind are unavailing, we are advised to use spirit of ammonia, tincture of cantharides, &c. It is also necessary to persevere for a long time in these remedies, even though the skin may become red and tender. Jörg is an advocate likewise for applying compresses to the parts dipped in such stimulating fluids, and kept constantly wet with them. Thus he calculates on maintaining the effects of their operation without interruption.

If the complaint be considerable in degree, and the head and neck much distorted, we are advised to combine with the foregoing means what are termed *manipulations*, which consist in manual endeavours to obtain an elongation of the contracted muscles, especially the sterno-cleido-mastoideus. In these manœuvres, we are directed to rub with one hand the muscle upwards, and at the same time to try to move the head in the same direction. With the other hand we are to bring the head into its natural position, and keep it there, so that the contracted muscles may be extended as much as possible. The greater their spasmodic contraction is, the more must we rub them in the direction above specified, even as long as a quarter or half an hour at a time; and the plan must be repeated once, twice, or thrice a day, until the head will remain quite straight, or until that side of the neck, which was previously convex, has become concave, and *vice versa*. Besides these *manipulations*, the head and face should be moved together into a perfectly upright posture, laterally, and especially towards the side to which they could not be turned, owing to the contracted state of the muscles. By these means, the patient will soon acquire the faculty of moving the neck to one side, which must always be a desideratum in the treatment.

Professor Jörg says, he has not deemed it necessary to mention electricity and galvanism as remedies, which may be joined with those above recommended. Whoever likes to try them, however, should only apply them to those muscles which are in a state of tension; for every stimulus must be improper for such as are contracted.

This author does not say much in favour of the warm bath as a remedy for wry-necks, in which cases he owns he has never made trial of it. All his patients have been children from one to nine years of age; and he thinks it would have been difficult, and even dangerous in some circumstances, to have immersed them sufficiently in the warm water to cover their necks. These are the only reasons which he gives for not having tried so important a remedy for the wry-neck as the warm bath.

One of the principal means for the cure of a wry-neck consists in a mechanical apparatus, by which the head is brought into a straight position, the contracted muscles are elongated, and others, which are on the stretch, kept in a state of rest and relaxation. It may be said, indeed, that the patient should be able to put his head and neck in this posture himself, and that no mechanical apparatus is requisite. But such posture can only be adopted by making a great effort, and even then imperfectly. Hence the best inclined patients soon give up the attempt, and the head

becomes depressed again. For children who cannot be persuaded to observe regularly the desirable position, the apparatus is more essential than for many adults. Several other writers had entertained this opinion previously to professor Jörg. Köhlers, Bernstein, and other authors, recommend a variety of mechanical contrivances for the cure of the wry-neck. None of these, however, have answered the expectations of professor Jörg, who has felt himself called upon to make an invention of his own. In the construction of his machine, he went upon the following principles: 1. That its operation should be effected by means of a spring. 2. That the action of the stretched enfeebled sterno-cleido-mastoideus should be strengthened, and the equilibrium between it and its fellow thereby re-established.

The apparatus consists of a leather pair of stays, and of a band or fillet which goes round the head. On the centre of the fore-part of the stays is a kind of pulley, or wheel, which admits of being turned to the right or left, and then becomes fixed by means of a spring. From this apparatus a band proceeds up the patient's neck to the fillet, placed round the head, and to which it is fastened directly behind the ear, close to the mastoid process. This band lies in the same direction as the lengthened sterno-cleido-mastoideus muscle, and when drawn towards the breast by the wheel, it produces the same effect as would arise from an increase of strength in the action of that muscle. In short, it pulls the mastoid process downwards and forwards towards the sternum, counteracts the influence of the opposite muscle of the same name, and thus rectifies the position of the head.

But this band, says professor Jörg, does not merely draw down the side of the head which is too elevated, it also tends to put the neck in a straight position. It was above explained, that a wry-neck is always more or less twisted, in consequence of the contraction of one of the sterno-cleido-mastoidei, and thus the mouth does not lie in a direct line perpendicularly above the centre of the sternum, but to one side of this point. The action of the preceding band, by drawing forwards as well as downwards towards the middle of the breast, the mastoid process evidently tends to counteract the effect produced by the wrong action of the faulty muscle of the opposite side.

Professor Jörg makes his patients wear the apparatus day and night, and he does not even take it off when the frictions are made. The band is to be tightened and regulated according to the effects produced. Particular care, however, must be taken not to make it too tight at first.

When by perseverance in the use of this apparatus, and the other means above recommended, the neck has been put into a proper position again, it usually happens that the head itself continues inclined too much forward; an effect which the contracted sterno-cleido-mastoideus, and its antagonist the band, both tend to promote. Something, therefore, must be done for the alleviation of this deformity. With this view, Jörg removes the above band from the breast, carries it under the arm, and through a ring at the side of the leather stays or corsets, and thence to the fillet round the head, where it is fastened in the same place as before. In this manner, the head will be considerably elevated, while still the object of counteracting the shortened sterno-cleido-mastoideus of the opposite side is not neglected. The ring hinders the band from hurting the axilla, and keeps it from following the motions of the shoulder. The preceding author lets his patients, towards the latter part of the treatment, wear the apparatus in this way a long while; yet sometimes he applies it in both modes alternately, with
a design

a design of habituating the muscles of the head and neck to different postures.

Together with this treatment, professor Jörg enjoins attention to every thing which tends to improve the health, especially a proper nourishing diet, pure air, &c. One thing he insists upon as essential, *viz.* that during work or repose, sleeping or awake, the patient constantly keep the head and neck in the right position. Hence children must be most vigilantly observed, as they soon forget what is told them; and the posture in which they lie when asleep must be attended to, as it is frequently a bad one. Jörg recommends laying their heads on firm round bolsters filled with horse-hair, and placing them on the side on which the muscles are contracted. The bed should be flat, and not sink, in order that the shoulder may not be depressed. In this position, the head will be pressed and inclined towards the opposite side. The patients must also be forbidden to do any kind of labour which will oblige them to hold their heads in a hurtful position; but Jörg rather commends dancing and the military exercise, as accustoming the patient to hold his head as he ought to do.

When the bones are concerned, the above apparatus and treatment will not be effectual; and particular machinery adapted to the case must be employed.

Frequently the curative means are prematurely discontinued, and the disorder recurs. It is commonly imagined, that when the head and neck can be brought straight, every thing is accomplished. But, as Jörg remarks, it is wrong to consider this period the completion of the cure; for, when the head and neck can be kept every day several hours in a right posture, without any machinery, the convalescents soon become fatigued, as it cannot be at first done without exertion. It is only when both sterno-cleido-mastoidei seem to be formed alike; when one is not tender than the other; and when, consequently, the equilibrium betwixt them is re-established; when also one side of the neck is as prominent and well-formed as the other; and when the head can be brought into the right position naturally, and without any effort; that the cure ought to be regarded as accomplished. The machinery may now be gradually relinquished with safety. At first it is to be taken off for an hour at a time every day, and the period of its discontinuance is to be lengthened by degrees, until at length it is entirely laid aside. For the foregoing excellent observations we are indebted to professor Jörg of Leipzig, whose publication on the deformities of the human body is entitled in German "Ueber die Verkümmungen des Menschlichen Körpers und eine rationelle und sichere Heilart derselben." Leipzig, 1816, 4to.

This author has not mentioned or given any opinion respecting the plan which was proposed by Mr. Sharp, of dividing and even cutting out a portion of the sterno-cleido-mastoideus muscle, which appears to act with too much power.

Mr. Gooch cured a patient by merely dividing the skin and platysma myoides muscle; a kind of case which Jörg thinks infrequent. Mr. Gooch also sometimes employed machinery with success.

WRY-NECK, a disease of the spasmodic kind in sheep, in which the head is drawn forcibly to one side, and the animal disabled from walking. The cure is to be effected by the use of calomel with opium in pretty full doses; putting the animal into a dry well-grassed pasture during the time, and avoiding cold and moisture.

WRY-NECK, *Jynx*, in *Ornithology*, a bird called also the *torquilla*, which Linnæus has made a distinct genus of the *picæ*, under the denomination of *yunn*: the characters of

which are, that the bill is slender, round, and pointed; the nostrils are concave and naked; the tongue is very long, very slender, cylindric, and terminated by a hard point; and the feet are formed for climbing.

There is only one species, *viz.* the *jynx torquilla*. The colours of this bird are elegantly pencilled, though its plumage is marked with the plainest kinds: a list of black and ferruginous strokes divides the top of the head and back; the sides of the head and neck are ash-coloured, beautifully traversed with fine lines of black and reddish-brown; the quill-feathers are dusky, but each web is marked with rust-coloured spots; the chin and breast are of a light yellowish-brown, adorned with sharp-pointed bars of black; the tail consists of ten feathers, broad at their ends and weak, of a pale ash-colour, powdered with black and red, and marked with four equidistant bars of black: the irides are of a yellowish colour.

The wry-neck, Mr. Pennant apprehends, is a bird of passage, appearing with us in the spring before the cuckoo. Its note is like that of the kestrel, a quick-repeated squeak: its eggs are white, with a very thin shell; this bird builds in the hollows of trees, making its nest of dry grass. It has a very whimsical way of turning and twisting its neck about, and bringing its head over its shoulders, whence it had its name *torquilla*, and its English one of wry-neck: it has also the faculty of erecting the feathers of the head like those of the jay. It feeds on ants, which it very dexterously transfixes with the bony and sharp end of its tongue, and then draws them into its mouth. Ray and Pennant.

WRYNOSE, in *Geography*, a mountain of England, on which are three stones, marking the boundaries of the three counties of Lancaster, Cumberland, and Westmoreland; 12 miles S. of Ravenglass.

WSCHESTAD, a town of Bohemia, in the circle of Kaurzim; 10 miles N.W. of Kofeteletz.

WSETIN, a town of Moravia, in the circle of Hradisch; 23 miles N.E. of Hradisch.

WUIPENS. See WIPPINGEN.

WULDA, a town of Bohemia, in the circle of Bechin; 12 miles S.W. of Crumau.

WULFEN, a town of Westphalia, in the bishopric of Osnabruck; 8 miles E.N.E. of Osnabruck.

WULFENIA, in *Botany*, was so named by professor Jacquin, in honour of his highly deserving friend, and constant botanical correspondent, the Rev. Francis Xavier von Wulfen, professor of natural philosophy and mathematics at Klagenfurt, in Carniola, to which charge he was appointed in 1762, and where he died March 17, 1806, aged seventy-eight. Amid the duties of his professorship, and the more serious calls of his ecclesiastical station, which he fulfilled by the most exemplary and active benevolence and charity to all within his reach, his favourite pursuit was the study of the botany and mineralogy of the surrounding country. His numerous contributions to the publications of Jacquin, on the rare plants of Carniola and Carinthia, constitute a treasure of the most valuable and original information. He writes with the ardour of a real lover of nature, and we have nothing to disapprove, except somewhat of the diffuse, and what Linnæus terms "oratorical," style, in the descriptive parts of his writings, where terseness and precision are most desirable, however agreeable the graces of oratory, and the expression of taste and feeling, may be in any accompanying remarks. The *Flora Lapponica* of Linnæus is our standard of perfection in this respect. Wulfen was an accomplished scholar, a man of the most amiable and elevated character, who adorns every thing that he touches, and

and who lived and died beloved and revered by men of all ranks, and of every persuasion. As he lived remote from the scientific circles of Europe, it is no wonder if, in the abstruse study of cryptogamic botany, he fell into some errors, especially relative to the *Lichen* tribe, a part of which the writer of this article presumed to correct, in a paper printed in the Transactions of the Linn. Soc. v. 2. p. 10, certainly without intending any disrespect for the excellent author, though a German writer of a more vulgar stamp, by mis-translation and misrepresentation, tried to excite them to enmity, but in vain. He may be pardoned for the sake of the great man whom he, though unskilfully, meant to defend, and for his own services to science, though of inferior pretensions. Wulfen is reported to have left behind him in MS. a complete *Flora Norica*, descriptive of the vegetable productions of a particular part of Carniola, an *Agrotopographia*, and several other works, rich in practical and scientific observations. Of these, it is to be hoped the learned world will not be deprived.—Jacq. Misc. Austr. v. 2. 62. t. 8. f. 1. Schreb. Gen. 16. Willd. Sp. Pl. v. 1. 78. Vahl Enum. v. 1. 86. Mart. Mill. Dict. v. 4. Sm. Transf. of Linn. Soc. v. 6. 96. (Bonarota; Mich. Gen. 9. t. 15. Pæderota; Juss. 120. Lamarck Dict. v. 4. 692. Illustr. t. 13, but not the original *Pæderota* of Linnæus. See Tr. of Linn. Soc. as above.)—Class and order, *Dianthria Monogynia*. Nat. Ord. *Personata*, Linn. *Scrophularia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, linear-awlshaped, equal, erect, permanent segments. *Cor.* of one petal, ringent: tube gibbous, and nearly globose at the base: limb two-lipped; upper lip shortest, undivided, or slightly notched, vaulted, acute; lower longest, deflexed, three-lobed. *Stam.* Filaments two, thread-shaped, ascending, shorter than the upper lip; anthers roundish. *Pist.* Germen superior, ovate-oblong, compressed; style thread-shaped, twice as long as the calyx; stigma capitate. *Peric.* Capsule ovate, compressed, furrowed at each side, of two cells and two divided valves, bursting at the summit. *Seeds* numerous, roundish.

Ess. Ch. Corolla tubular, ringent; upper lip vaulted; lower three-cleft. Calyx in five deep segments. Capsule of two cells, and two cloven valves.

Obs. This genus is certainly next akin to *VERONICA*, under which article we have recorded a remark to that effect made by Mr. Brown. The essential difference, however, between these two genera resides in the limb of the *corolla*, which in *Veronica* is wheel-shaped, its lower segment narrowest; a character of more importance than the proportion of the tube, that part being, in a few species, nearly as much elongated as in the present genus. If any of those species should prove to have a ringent *corolla*, whose upper lip is vaulted, and the lower three-lobed, they must be removed to *Wulfenia*; but we discover nothing of this in *V. sibirica* or *virginica*, whose limb is truly that of a *Veronica*. Whether the throat be bearded in every species of *Wulfenia*, we are not certain; nor is that circumstance material, any more than the valves of the *capsule* being cloven or not, the same difference existing between different species of *Veronica*, as has already been mentioned in its proper place. The five-cleft *calyx*, indicated by Linnæus as the mark of *Pæderota*, is found in the two *Veronica* just named, as well as in some less ambiguous species, as *V. austriaca*, *multifida*, *Teucrium*, and *latifolia*, though in these last the fifth segment varies in size, is occasionally absent, and is always unequal to the others.

1. *W. Bonarota*. Blue Leafy Wulfenia. Sm. n. 1. Vahl n. 1. (*Pæderota Bonarota*; Linn. Sp. Pl. 20.

Willd. Sp. Pl. v. 1. 77. Jacq. Austr. append. t. 39. P. cærulea; Linn. Suppl. 84. Lamarck Illustr. v. 1. 48. t. 13. f. 1. Bonarota montana italica, chamædryos folio, flore cæruleo; Mich. Gen. 19. t. 15. f. 1; also f. 2, with rounder leaves, and a more dense spike. Chamædryos montis Sumani; Bauh. Hist. v. 3. 289.)—Stem leafy. Upper lip of the corolla entire. Leaves roundish-ovate.—Native of the mountains of Italy and Carniola; perennial: a stranger in our gardens, as well as the two following. The root is somewhat creeping. Stems simple, erect, five or six inches high, downy like the rest of the herbage, each bearing four or five pair of roundish-ovate leaves, about an inch long, with broad, rather shallow serratures. Cluster terminal, foliary, ovate-oblong, of several pretty blue flowers, accompanied by lanceolate bractæas. Calyx hairy. The corolla is decidedly ringent, with a concave upper lip, and the valves of the capsule split at the summit, each into two sharp points.

2. *W. Ageria*. Yellow Leafy Wulfenia. Sm. n. 2. Vahl n. 2. (*Pæderota Ageria*; Linn. Mant. 171, including Bauhin's synonym. Willd. Sp. Pl. v. 1. 77. P. lutea; Scop. Ann. 2. 41. Lamarck n. 3. excluding the reference to Bauhin. Linn. Suppl. 84. P. Bonarota; Jacq. Hort. Vind. v. 2. 55. t. 121. Bonarota montana italica, chamædryos folio minus crenato, spicâ luteâ; Mich. Gen. 19.)—Stem leafy. Upper lip of the corolla cloven. Leaves ovate-lanceolate, elongated at the point.—Native of Carniola and Italy, in places where, according to Scopoli, the former is not found. Great confusion respecting these two plants has long existed. Linnæus and Scopoli sometimes considered them as varieties of each other, and when they made them distinct, they misapplied their synonyms. The present is said to be distinguished by the emarginate, or cloven, upper lip of the corolla, which, nevertheless, Jacquin's figure does not express, and which is but slightly perceptible in our dried specimens. The leaves differ materially in their more elongated form, and narrower, more copious, serratures; the lower ones being alternate, as noticed by Scopoli, is but a casual occurrence. The corolla is of a pale sulphur-colour, not blue. Calyx smooth. The style in both these species is full as long in proportion to the calyx and corolla as in the following, though described, in the generic character of *Pæderota* by Linnæus, as only the length of the stamens.

The specific name of *Ageria*, given by Linnæus to what had much better have been called *lutea*, is intended to commemorate Nicholas Agerius, a friend of John and Caspar Bauhin, who sent our *W. Bonarota* to the former, and is mentioned by him in several places. His name occurs in Linn. Sp. Pl. 1670, as the original discoverer of *Verbascum Thapsi*. Haller speaks of him as having published, at Strasburg, in 1625, a quarto dissertation de *Zoophytis*; and another in 1629, de *Animâ vegetativâ*; works not mentioned in Sir Joseph Banks's rich catalogue, and therefore, doubtless, very rare.

3. *W. carinthiaca*. Carinthian Wulfenia. Sm. n. 3. Willd. n. 1. Vahl n. 3. Jacq. Misc. Austr. v. 2. 60. Ic. Rar. t. 2. (*Pæderota nudicaulis*; Lamarck Dict. v. 4. 692. Illustr. v. 1. 48. t. 13. f. 2.)—Stem naked. Leaves crenate.—Found by Wulfen, in a rich soil, among limestone rocks, on the loftiest and most craggy mountains of Carinthia, flowering in the middle of July. The root is creeping, perennial, half as thick as the middle finger. Leaves several together in a tuft, all radical, obovate, obtuse, four or five inches long, doubly or unequally crenate, smooth and shining, except the strong mid-rib, which is hairy at the back; their base tapering into a winged footstalk.

Flowers

Flowers large and handsome, of a fine blue, crowded numerously into a dense cluster, supported by an upright, round, firm, unbranched, leafless, though somewhat scaly and slightly hairy, solitary, radical *stalk*, twice or thrice the height of the leaves. After flowering, the *cluster* becomes three or four inches long, and the permanent *calyces* turn reddish. The *capsules* are each one-third of an inch in length, brown, abrupt, scarcely exceeding the calyx, soon splitting into four parts at the top. The error of the specific name in Lamarck's synonym, *P. Wulfenia*, for *P. nudicaulis*, in Vahl and Willdenow, is copied by the former from the latter.

WULFRADT, in *Geography*, a town of the duchy of Berg; 3 miles N.E. of Medman.

WULFSDORP, a town of the duchy of Holstein; 11 miles N.N.W. of Lubeck.

WULFSFELDE, a town of the duchy of Holstein; 12 miles N.W. of Lubeck.

WULFTEN, a town of Westphalia, in the bishopric of Osnabruck; 2 miles S.W. of Osnabruck.

WULLED, a town of Arabia, in the province of Yemen; 46 miles S.E. of Loheia.

WULLERSDORFF, a town of Austria; 2 miles S.E. of Gunderdorff.

WULLI, *Mountains of*, mountains of Persia, which extend from the vicinity of Shatzan, across to the lake of Vaikind, and form one range with that on the N. of Mekran, called Gehelabad by La Rochette.

WULPERODE, a town of Westphalia, in the principality of Halberstadt; 4 miles W. of Osterwick.

WULTZESHOFEN, a town of Austria; 1 mile S.W. of Laab.

WULVESHEVED, or WULVESHEAD. See WOLFESHEAD.

WUMBLE, in *Rural Economy*, the provincial name of an auger. It is sometimes written wummle and wimble.

WUMME, in *Geography*, a river of the duchy of Bremen, which runs into the Weser, about 6 miles N.W. of Bremen.

WUNALACHTIKOS, a tribe of Delaware Indians.

WUNNENBERG, a town of Westphalia, in the bishopric of Paderborn, which received its name from a victory which Charlemagne gained in the year 974 over the Saxons; 14 miles S. of Paderborn. N. lat. $51^{\circ} 29'$. E. long. $8^{\circ} 7'$.

WUNSCHELBERG, or HRADECK, a town of Silesia, in the county of Glatz. Here are manufactures of thread, cloth, and variety of stuffs; 10 miles N.W. of Glatz. N. lat. $50^{\circ} 19'$. E. long. $16^{\circ} 15'$.

WUNSCHUECH, a town of Stiria; 8 miles S. of Gratz.

WUNSEES, a town of Germany, in the principality of Bayreuth; 13 miles W. of Bayreuth.

WUNSIEDEL, a town of Germany, in the principality of Bayreuth, on the Fichtelberg; near it are mines of copper and iron, and quarries of marble; 34 miles E. of Bayreuth. N. lat. $50^{\circ} 3'$. E. long. $12^{\circ} 3'$.

WUNSTORF, a town of Westphalia, in the principality of Calenberg, the chief place of a county, which became extinct in the year 1533; 10 miles W.N.W. of Hanover. N. lat. $52^{\circ} 27'$. E. long. $9^{\circ} 32'$.

WUNT, in *Agriculture*, a term provincially applied to the mole.

WUNT-Hillock, a word signifying a mole-hill. See MOLE and MOLE-Hill.

WUNTZ, in *Geography*, a town of the county of Henneberg; 6 miles N.W. of Meinungen.

WURBEN, a town of Silesia, in the principality of Schweidnitz; 4 miles N. of Schweidnitz.

WURBENTHAL, a town of Silesia, in the principality of Troppau; 13 miles W. of Jajerndorf. N. lat. $49^{\circ} 57'$. E. long. $17^{\circ} 15'$.

WURFE, in *Commerce*, a denomination distinguishing a certain quantity of inferior silver coins in Germany; thus, a wurfe denotes 5 pieces of 17 or of 7 creutzers; and 12 wurfe of 17 creutzer pieces make 17 florins, and 12 wurfe of 7 creutzer pieces make 7 florins.

WURGLAU, or GUERGALA, in *Geography*. See WERGELA.

WURL, a river of Westphalia, which runs into the Ems, near Rietberg.

WURLITZHAI DT, a town of Germany, in the principality of Culmbach; 7 miles S.E. of Hof.

WURMBEA, in *Botany*, is dedicated by Thunberg to the honour of baron Frederick van Wurmb, secretary to the Academy of Sciences at Batavia, whom he celebrates for great skill in Natural History, and other scientific pursuits, and who rendered him important services in his expedition to Japan.—Thunb. Nov. Gen. 18. t. 1. Schreb. Gen. 239. Willd. Sp. Pl. v. 2. 265. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 325. Poir. in Lamarck Dict. v. 8. 802. Lamarck Illustr. t. 270. (Melanthii species; Juss. 47. Thunb. Prodr. 67.)—Class and order, *Hexandria Trigynia*. Nat. Ord. *Coronaria*, Linn. *Junci*, Juss.

Gen. Ch. *Cal.* none; unless, like Thunberg, we take the corolla for such. *Cor.* of one petal, tubular, permanent: tube with six angles, abrupt at the base: limb in six deep, lanceolate, acute, equal, erect, or spreading segments, usually about the length of the tube. *Stam.* Filaments six, thread-shaped, erect, inserted into the mouth of the tube, and shorter than the limb; anthers roundish, of two lobes. *Pist.* Germen superior, triangular, furrowed, smooth; styles three, awl-shaped, triangular, the length of the filaments; stigmas obtuse. *Peric.* Capsule invested with the withered corolla, oblong, with three angles and three furrows, consisting of three cells, separating from the top half way down. *Seeds* numerous, round.

Ess. Ch. Calyx none. Corolla in six deep equal segments, with an hexagonal tube. Stamens inserted into the mouth of the tube. Capsule superior.

Obs. Under the genus MELANTHIUM, (see that article,) we have expressed a determination of reducing the present genus to that. By a casual oversight, however, the species which compose *Wurmbea* were there omitted. Having examined them with more attention, and particularly with respect to ORNITHOGLOSSUM, which the reader will find in its proper place, our opinion has changed. The latter genus, to which *Melanthium indicum* perhaps really belongs, has most resemblance to *Wurmbea* in habit, and in the general aspect of the *flowers*; though most widely estranged therefrom in its generic character, founded on the insertion of the *stamens*. If *Ornithoglossum* be retained, *Wurmbea* must. No difficulty attends its essential character, which is obvious enough, in the pale hexangular tube, abrupt or gibbous at the base, as if furnished with six small spurs. The Linnæan herbarium shews, that Linnæus himself had established the present genus, and dedicated it to his friend Sparrmann, by whom his specimens were brought to Europe. There is a singular remark in Thunberg, of *Wurmbea* having, "without all doubt," been produced from *Melanthium ciliatum*!

1. *W. pumila*. Dwarf *Wurmbea*. Willd. n. 1. (*W. capensis* α ; Thunb. Nov. Gen. 19. t. 1. f. 7.)—Cluster of three

three or four flowers. Tube the length of the limb.—Native of the Cape of Good Hope, in sandy ground, at the foot of small hills, flowering in August or September. The *root* is a small globular bulb, as in all the rest, sunk deep into the earth. Whole *herb* but an inch high, with two or three short, sheathing, lanceolate *leaves*. *Cluster* hardly rising above the foliage, of three or four, rarely more, erect white *flowers*, on longish partial stalks, not sessile, or spiked, if Thunberg's figure be correct, like the other species. The margins of the segments of the *flower* are purple, and there are spots of the same colour just above the mouth of its tube. The *stamens* are white. *Thunberg*.

2. *W. campanulata*. Bell-flowered Wurmbea. Willd. n. 2. Ait. n. 2. (*W. capensis* γ; Thunb. Nov. Gen. 19. t. 1. f. β. Lamarck f. 1. *Melanthium monopetalum*; Linn. Suppl. 213. Ker in Curt. Mag. t. 1291.)—Tube of the corolla bell-shaped, the length of the limb, which is twice as long as the stamens. Spike dense, cylindrical.—Native of the same country. Sent to Kew garden, by Mr. Masson, in 1788. It flowers in the green-house in May and June. The *bulb* is ovate. *Stem* solitary, simple, leafy, from three to five inches high; zigzag, tapering, and pale, in the part which is below the surface of the ground. *Leaves* three or four, alternate, widely spreading, or recurved, much longer than the stem, but not elevated above it, tapering, channelled, rather glaucous, smooth; their base dilated and sheathing. *Spike* terminal, erect, two or three inches long, of numerous, sessile, white *flowers*, whose limb is rather concave, its edges brown in our specimens, answering to Thunberg's description, though that circumstance is not expressed in the Botanical Magazine. *Stamens* white, spreading, not half the length of the limb, with yellow *anthers*.

3. *W. purpurea*. Purple Wurmbea. Banks MSS. Ait. n. 2. (*W. capensis* β; Thunb. Nov. Gen. 19. Andr. Repos. t. 221. *W. campanulata* β; Willd. n. 2. *Melanthium spicatum*; Curt. Mag. t. 694.)—Tube of the corolla much shorter than the widely spreading limb.—Native of the Cape. Sent to Kew in 1788, by Mr. Masson. This has the herbage of the last, but the *spike* is rather more lax, and the *flowers* all over of a dark violet purple, except the yellow *anthers*, have a much shorter *tube*, and longer *limb*.

4. *W. longiflora*. Long-flowered Wurmbea. Willd. n. 3. (*W. capensis* δ; Thunb. Nov. Gen. 19. t. 1. f. α. Lamarck f. 2.)—Spike taller than the leaves. Tube of the corolla twice the length of the limb.—Found at the Cape of Good Hope, on sandy hills in various places. A taller larger plant than any of the preceding; its *leaves* much broader at the base. *Spike* three or four inches long, rather lax, many-flowered, with a zigzag angular *stalk*. *Flowers* entirely white; their *tube* near an inch long; *limb* about half that length, widely spreading. *Stamens* full half the length of the limb. That all these species should have been considered as varieties only, appears as strange as any other particular in the history of the present genus. The Linnæan herbarium proves the *Melanthium monopetalum* of the Supplementum to be not this, but the *W. campanulata*.

WURMBERG, in *Geography*, a town of the duchy of Stiria; 6 miles N.W. of Pettau.

WURMSEE, a lake of Bavaria; 13 miles S.W. of Munich.

WURST, a Russian measure. See WERST.

WURSUREE, in *Geography*, a town of Hindoostan, in Guzerat; 32 miles N.E. of Chitpour.

WURTEMBERG, late a duchy and now a kingdom of Germany, bounded on the north by the bishopric of

Spire, the palatinate of the Rhine, the county of Hohenlohe, and territories of the city of Hall in Swabia; on the east by the county of Limburg, the territories of the imperial towns Gemund and Ulm, and county of Oettingen; on the south by Austrian Swabia, the territories of Furstenberg, Zwifalten, Rothweil, and the Brigau; and on the west by the marquisates of Baden Baden, and Baden Durlach: about 64 miles from north to south, and about as much from east to west, comprehending about 3200 square miles. This kingdom consists of a great number of counties and lordships, some of which were purchased, some devolved to it by marriage, and others were acquired by conquest. It is beyond dispute the most considerable and fertile part of the circle of Swabia, and may indeed be said to be, after Saxony, one of the best countries in all Germany. From its natural disposition, the country consists of three tracts, which are all remarkably different. Of these, the lowest and warmest is the north, called Unterland, reaching from Heilbronn to Stuttgart. This duchy abounds so in grain, that it exports considerable quantities; but this grain is chiefly spelt, rye and wheat being much less cultivated here. Of all the other sorts of grain, however, here is also a sufficiency, even for export. Flax and hemp are also cultivated, and the former of these thrives best in the cold parts. The valleys, some of which are seven or eight miles in length, are covered as it were with forests of fruit-trees, of which there is no scarcity in the other parts of this country, cyder and perry being the liquors drank in common by the country people, when wine happens to be dear. This duchy abounds likewise in very rich, palatable, and wholesome wines, called by the general name of Neckar wines, though each has a particular title of its own, which it receives from the parts where it grows. The grapes also, which yield the best wines, bear the appellation of the countries whence the sets were first brought, as the Chiavenna, Valteline, Tyrolese, and Hungarian. The vineyards of the duchy of Wurtemberg have been greatly improved by shoots from France, Italy, Greece, Hungary, Cyprus, and even Schiras in Persia. The cultivation of silk was revived under duke Charles. The forests of this country are considerably lessened. The consumption of oak, in particular, has been very large. The mountains of the Black forest on the W. and those of the Alt on the S. and E., not only diversify the face of the country, but supply timber, food, and wines. Most parts of the country abound in game; near Frudenstadt, and near Konigswart, are mines of silver and copper; of silver at Konigstein, and of copper at Guttach: near Hornberg iron is also found. Of minerals, *terra sigillata*, which is reckoned preferable to that of Malta, and a fine clay for earthenware, as also porcelain, which is worked at Calv; fine variegated marbles, some of which are equal to those of Italy; and remarkably transparent alabaster, agate, crystalline pebbles, black amber, or rather obsidian, fine mill-stones, &c.: and at Sulz there are salt-works. Among the baths in Wurtemberg, the most celebrated is that of the Wildbad. The principal rivers are, the Neckar, the Enz, and the Nagold. The number of inhabitants in this state is known to precision, an exact inquiry being made every year by the general superintendants, and reported to the annual synod; they are now about 600,000. The state contains 68 cities and towns, with about 1200 boroughs, market-towns, villages, and hamlets. The revenue is computed at 245,000*l.*, and the military force at 6000. The established religion of this country is Lutheranism, and though duke Charles Alexander embraced the Roman, yet in the years 1729, 1732, and 1733, he gave assurances to the states, in formal instru-

ments, that no change or innovation should be made in the Lutheran religion in any part of the whole duchy, and that in all the churches and schools throughout the duchy, and the countries thereto belonging, no other religion than that of Lutheranism should be taught: that no Catholic churches, chapels, altars, or images, should be erected or set up, nor any such as were decayed or forsaken again used. The Calvinists only are tolerated here, and their place of worship at Stuttgard is a private house. In this duchy are also some Waldenses, who are either husbandmen or farmers, and live in the Italian villages, as they are called, some few towns alone excepted; where they have established manufactures of hats and stockings, and are allowed the public exercise of their religion. The toleration of the Jews here was abolished by an edict of duke Christopher, that of two or three families at Stuttgard excepted, under the particular protection of the court. The church is governed by four superintendants, styled abbots, and 38 rural deans; a synod is annually held in the autumn. Education, and particularly that of ecclesiastics, is favoured by laudable institutions; the seminary of Tubingen used to accommodate about 300 students; and at Stuttgard there is a public academy. Here are manufactures of pottery, glass, woollen, linen, and silk, which, with the natural products of the country, supply a considerable export. The imports are by Frankfort on the Maine. The chief city is Stuttgard, and the second town is Tubingen. The other towns are numerous, but small; and the villages are thickly placed in a populous and flourishing country. The origin of the princely house is somewhat obscure and uncertain. It is certain, however, that there were counts of Wurtemberg at the beginning of the twelfth century. In 1802 Wurtemberg was created an electorate of the empire; and in 1806 was erected into a kingdom. The castle of Wurtemberg, which gave name to the duchy, is situated 4 miles E. from Stuttgard. By the treaty of Presburg in 1805, the king of Wurtemberg acquired several important reserves.

WURZBURG, a town of Germany, in the county of Erbach; 3 miles E. of Erbach.

WURTZEN, a mountain of Carinthia; 8 miles S. of Villach.

WURWAMA, a town of Hindooستان, in Guzerat, on the south side of the gulf of Cutch; 40 miles N.E. of Noanagur.

WURWAY, a river of North Wales, which runs into the Vurney, 3 miles S. of Llanvilling, in the county of Montgomery.

WURZACH, a town of Germany, in the county of Waldburg, on the Aitrach; 26 miles N.W. of Kempten. N. lat. 48° 0'. E. long. 9° 52'.

WURZBACH, a river of Germany, which runs into the Klein Enz, 2 miles E. of Wildbad.

WURZBURG, a duchy, late a bishopric, bounded on the north by the county of Henneberg and principality of Coburg; on the east by the bishopric of Bamberg, the margravate of Anspach, and the county of Castell; on the south by the county of Hohenlohe; and on the west by Mergentheim, county of Wertheim, electorate of Mentz, and the bishopric of Fulda; about 80 miles in length, and 64 in breadth. The territory of Wurzburg is fertile in corn, pastures, and divers sorts of fruits and plants, as also in wine, the very best Franconian vines growing in it. The prevailing religion is the Roman Catholic; but there are also Lutheran and Calvinist churches within the ecclesiastical jurisdiction and territory of Wurzburg, which from time to time preferred to the diets of the empire grievous complaints of oppression and injustice. In the

sixteenth century, this bishopric abounded with Protestant inhabitants. The bishopric was not founded here till 741. In the year 1752, pope Benedict XIV. granted them the privileges of bearing the archiepiscopal pall and crosses; but in other respects they were suffragans to the archbishops of Mentz. This prince and bishop maintained five regiments of foot and horse, military affairs being subject to the aulic council of war. In 1806 Wurzburg was secularized, soon after erected into a duchy, and given to the archduke Ferdinand. The number of inhabitants is computed at 200,000. By the treaty of Presburg in 1805, the new kingdom of Bavaria, to which Wurzburg had been before assigned, acquired several important additions.

WURZBURG, a city of Germany, and capital of a duchy, late residence of the bishop. It is situated on the Maine, well fortified, and defended by a fortress, situated on a rock without the town; in which fortress is an episcopal palace, and a church, supposed to be the oldest in Franconia. The town is divided into four quarters and four suburbs, in which are, a new palace, built in the beginning of the eighteenth century, a cathedral, several collegiate and parish churches, colleges, abbeys, and convents. The university was founded in the year 1403; and, after falling to decay, restored again in 1582. In August 1796, Wurzburg was taken by the French, but given up to the Austrians the month following; 50 miles E.S.E. of Frankfort on the Maine. N. lat. 49° 50'. E. long. 9° 59'.

WURZELBAU, or WURTZELBAU, JOHN PHILIP, in *Biography*, a German astronomer, was born at Nuremberg in 1651, and being diverted from his studies by a change of circumstances, devoted himself to mercantile pursuits. But in the midst of these occupations, he reserved his spare hours for reading, and acquainting himself with the French, Italian, and Spanish languages. His chief attention was directed to mathematics and astronomy. In 1684 and 1685 he made observations on an eclipse of the moon, which were printed; and in 1689 transmitted to the Royal Society communications pertaining to astronomy. In 1691 devoting himself more sedulously to the study of geometry and astronomy, the emperor Leopold, apprized of his merits, raised him and his heirs to the rank of nobility in 1692. In 1699 he was chosen one of the foreign associates of the Academy of Sciences at Paris, and in 1706 he became a member of the Academy of Berlin. Declining a removal to Dresden, with the offer of an annual salary of 1000 dollars and free lodging, he occupied himself in astronomical observations with instruments of his own invention and construction; and he built, at his residence in Nuremberg, an observatory consisting of an octagon turret, covered with copper, and resting on iron bars, which was placed on the top of the house, and which was moveable to every part of the heavens: it was furnished with an azimuth quadrant of five feet radius, a sextant of six feet, and other instruments; of which observatory he published an account at Nuremberg, 1697, fol. He published also other works, *ibid.* 1713, fol. and *ibid.* 1719, fol. Having published solar tables, &c. he died at Nuremberg in 1725. He published also various observations in the *Phil. Trans.* vol. xv. xvi. xvii. and vol. xxx.; and also at Nuremberg. Montucla. Weidler. *Gen. Biog.*

WURTZEN, or WURTZEN, in *Geography*, a town of Saxony, in the territory of Leipzig; the bailiwick of which extends over seventy-six villages, and twenty-two noble estates; anciently the see of a bishop, but in 1661, the estates of the foundation were annexed to the Leipzig circle. The town is situated on the Mulda; though not large in itself, it is much increased by its fauxbourgs, which contain

the citadel and cathedral. The beer brewed here is the chief article of trade, and is exported in great quantities; 14 miles E. of Leipzig. N. lat. $51^{\circ} 19'$. E. long. $12^{\circ} 42'$.

WUSEN, a town of Prussia, in the province of Ermland, on the Passarg; 25 miles W. of Heilsberg.

WUSHUTEE, or MEECH, a general term applied to all that country of the province of Mekran in Persia, lying to the westward, and on the parallel of Punjgoor or Panger, and forming the northern boundary of the Sandy Desert. It is represented to be a mountainous district, producing in some of its villages grain, sufficient for the consumption of the few wandering shepherds who inhabit them. Water is plentiful, except in April, May, and June; dates are also produced, and camels, sheep, and goats, are procurable, but not in great number. The people are rather a small delicate race: their arms are, a match-lock, sword, and shield; and each village has its own chief, who settles disputes that arise among the inhabitants.

WUSLACH, a town of Prussia, in the province of Ermland; 10 miles E. of Heilsberg.

WUSTENSAXEN, a town of Germany, in the principality of Wurzburg; 5 miles N. of Bischofsheim.

WUSTERHAUSEN, a town of the Middle Mark of Brandenburg; 11 miles S.S.E. of Berlin.—Also, a town of the Middle Mark of Brandenburg, on the Dosse; 36 miles N.W. of Berlin. N. lat. $52^{\circ} 53'$. E. long. $12^{\circ} 31'$.

WUSTERSDORF, a town of Austria; 9 miles S.W. of Laab.

WUSTHAL, a town of Germany, in the circle of the Lower Rhine; 4 miles N. of Rothenbach.

WUSTRO, a town of Westphalia, in the principality of Lunenburg Zelle, on the Jetze and the Dumme; 40 miles S.E. of Luneburg.

WUTACH, a river of Germany, which crosses the county of Stuhlingen, and runs into the Rhine, 10 miles below Lauffenburg.

WUTTOOR, a town of Hindoostan, in Dowlatabad; 6 miles E. of Junere.

WUTZKOW, a town of Hinder Pomerania: it is the last post stage bordering on Poland; 30 miles E. of Stolpe.

WYACONDA, a river of Louisiana, which runs into the Mississippi, N. lat. $39^{\circ} 46'$. W. long. $91^{\circ} 48'$.

WYALUSING, a township of Pennsylvania, in the county of Luzerne, with 576 inhabitants; 320 miles N. of Washington.

WYALUSING *Creek*, a river of Pennsylvania, which runs into the E. branch of the Susquehanna, N. lat. $41^{\circ} 40'$. W. long. $76^{\circ} 20'$.

WYANDOT, a town of North America, belonging to the United States: a tribe of Indians called Wyandots inhabit the neighbourhood; 6 miles S. of Sandusky.

WYASTON, a village in the hundred of Appletree, Derbyshire, England, situated 3 miles from Ashborne, and 137 from London. In the year 1811 it contained 16 houses, and 69 inhabitants.

WYAT, Sir THOMAS, in *Biography*, an English poet, was the son of Henry Wyatt, esq. of Allington-castle in Kent, and born in 1503. Having finished his education at Cambridge and Oxford, he travelled, as an envoy, into various parts of Europe, and acquired the favour of Henry VIII. whose good will was of very short duration; for either from a suspicion of his connection with Ann Boleyn, or the ill offices of Bonner, he was for some time imprisoned. After his liberation he retired to his castle of Allington, and being employed to conduct the ambassador of Charles V. from Falmouth to London he was seized with a fever, of which he died at Sherburn in 1541. In an elegy on his

death, his character was highly drawn in an encomium by the earl of Surrey, with whom he was intimate, as his fellow-labourer in polishing English poetry; though his strains are said to have been inferior to those of the earl of Surrey. Mr. Warton distinguishes him by the appellation of the first polished English satirist. His reputation was high, and Leland published a book of Latin verses on his death. His poems were printed with the editions of those of Surrey in 1559 and 1565, and since by Dr. Sewel, in 1717. His version of David's Psalms is much commended by Surrey and Leland; but it is not extant. Warton's Hist. of Eng. Poetry. Gen Biog.

WYBERTON, in *Geography*, a village and parish in the wapentake of Kirton, Holland division of the county of Lincoln; 2 miles from Boston, and 115 from London. It was returned in the year 1811 as containing 74 houses, occupied by 353 persons.

WYBOLDSTON, a village in the hundred of Barford, Bedfordshire, England, situated 8 miles from Biggleswade, and 2 miles from St. Neot's. The population is not separately returned, being included in the parish of Eaton-Socon.

WYBORG. See VIBORG.

WYBUNBURY, or WIBBUNBURY, a village in the hundred of Namptwich, county palatine of Chester, is situated on the borders of Staffordshire, about 3 miles E. from Namptwich. The church is a handsome structure, and contains a great variety of monuments and other sepulchral memorials. A school was built here nearly two centuries ago by subscription; the endowments are but small, though increased by occasional donations: the school is for boys, some of whom are taught reading only, others reading, writing, and arithmetic. The population return of the year 1811 states this village to contain 76 houses, and 353 inhabitants. The parish of Wybunbury is very extensive, and comprehends eighteen townships.—Lyttons's Magna Britannia, vol. ii. Cheshire, 1810.

WYCH-HOUSE, a house in which salt is boiled. (See SALT.) In the places where there are salt-springs, and salt-works are carried on at them, the work-house where the salt is made is always called the wych-house; and hence we may naturally conclude that *wych* was an old British word for salt, which is the more probable, as all the towns in which salt is made end in *wych*; as *Namptwyc*, *Droitwyc*, *Middlewyc*, &c.

WYCHERLEY, WILLIAM, in *Biography*, was born at Cleve, in Shropshire, about the year 1640; and in France, whither he went for his education, he conformed to the Roman Catholic religion. Upon his return to England a little while before the Restoration, he entered, without matriculation, as a gentleman-commoner at Queen's college, Oxford, and leaving it without a degree, took chambers in the Middle Temple. However, he abandoned the law, and addicted himself to the composition of comedies, the first of which was entitled "Love in a Wood, or St. James's Park," which brought him into notice in 1672; so that he became a favourite of the dukes of Cleveland, and of Villiers, the duke of Buckingham. He was also honoured by the attention of the king, and by promises of future promotion. His majesty, however, was displeased by his marriage with the countess of Drogheda, and the connection was unhappy. On occasion of her death, however, she settled her whole estate upon him, and his title being disputed, he was involved in law expences and other incumbrances, which occasioned his being committed to prison. Having remained in prison for seven years, he was liberated by king James II., who, delighted by seeing his comedy of

the "Plain Dealer," gave orders for the payment of his debts, and settled upon him a pension of 200*l.* a year.

His circumstances were still embarrassed, and though by his father's death he became a tenant of the estate to which he succeeded, he was not emancipated from his difficulties. Some time after he married a young woman, on whom he settled a jointure of 1500*l.*, humourously stipulating with her that she should not take an old man for her second husband, which condition, it is said, she promised faithfully to observe. He died in 1715, at the age of 75.

Besides the two comedies already mentioned, he composed "The Gentleman Dancing-Master," and "The Country-Wife." The last and the Plain Dealer are said to be the most noted. His plays, though commended by lord Rochester, are strongly marked with his own character,—“some wit and strength of delineation, with much coarseness and licentiousness.” He attacks vice, it is said, with the severity of a cynic, and the language of a libertine. A volume of poems published in 1704 was so unsuccessful, that he applied to Pope, who was a mere youth, to correct the versification. Dr. Johnson remarks, that “when Pope was sufficiently bold in his criticisms, and liberal in his alterations, the old scribbler was angry to see his pages defaced, and felt more pain from the detection than content from the amendment of his faults.” The posthumous works of Wycherley, in prose and verse, were published by Theobald in 1728, 8vo., but they are utterly forgotten. Biog. Brit. Johnson's Life of Pope. Gen. Biog.

WYCK, JOHN, was the son of Thomas Wyck, a painter of shipping and views of towns, of no very great celebrity, who was in England in the time of Charles II. John was born at Haerlem about the year 1640, and distinguished himself as a painter of battles and sieges, and sometimes of huntings and processions. He imitated the style of Wouvermans and Vander Meulen, but never obtained their neatness or finish, though his colour is oftentimes very agreeable. His execution is better upon a small than a larger scale. He died at Mortlake in 1702.

WYCK, in *Geography*, a part of the city of Maestricht, on the E. side of the Meuse, strongly fortified. See MAESTRICH. —Also, a small sea-port of Russia, on the W. coast of the island of Esel.

WYCK *op Zee*, a town of Holland, near the sea; 3 miles W. of Beverwick.

WYCK *te Duerstede*, a town of Holland, in the department of Utrecht, supposed to be mentioned by Tacitus, by the name of "Batavodurum," and said to have been built by Battus, prince of the Catti. It was granted, with its territory, to Rixfride, the seventh bishop of Utrecht, and his successors, for the zeal he had shewn in converting the infidels. Trithemius relates, that it was anciently three leagues in circumference, and had 55 parish-churches, and that it had been destroyed by the Normans and Danes three several times; 13 miles S.E. of Utrecht.

WYCLIFFE, a small village and parish in the wapentake of West Culling, North Riding of Yorkshire, England, is situated two miles N.E. from Greta-bridge; and in the year 1811 was returned as containing 26 houses, and 140 inhabitants.

WYCOMBE, HIGH, or *Chipping-Wycombe*, a large market and borough town in the hundred of Desborough, Buckinghamshire, England, is situated 34 miles S.E. from the county town, and 29 miles W. by N. from London, on the banks of a small river, which rises at West Wycombe, and, in its course through this parish, turns several corn and paper mills. A weekly market on Fridays has been held from time immemorial, and is a great mart for corn and

other articles: here is also an annual fair. This borough has sent members to parliament from the 28th year of Edward I.: the right of election is vested in the mayor, aldermen, bailiffs, and burghesses; and the number of voters is about 180. Edmund Waller, the poet, was one of the representatives in 1625; sir Edmund Verney, king Charles's standard-bearer, who fell at the battle of Edgehill, was elected to the parliaments of 1639 and 1640; and Thomas Scott, the regicide, was a member during the protectorate of Cromwell. The first incorporation of the town appears to have been in 1461; but the mayor and aldermen are mentioned in a record of the reign of Edward III.: the earliest charter now extant bears date 1586. The corporation consists of a mayor, twelve aldermen, a recorder, and other officers; formerly here was a high steward, but the office was annulled by a charter of Charles II.; yet since that time it has been held (by virtue of former charters) by the earl of Bridgewater, lord-chancellor Jefferies, and the marquis of Wharton. According to the population return of the year 1811, the town contained 494 houses and 2490 inhabitants: the parish is extensive, and includes several hamlets, which make an addition of 2266 to the population, and 449 to the number of houses. The manor of Wycombe having passed through a variety of families, was sold, together with the manors of Loakes and Windfors, or Chapel-fee, by Thomas Archdale, esq. in 1700 to Henry Petty, lord Shelburne, who bequeathed all his estates to his nephew, John Fitzmaurice, afterwards earl of Shelburne. His son, who in 1784 was created earl Wycombe and marquis of Lansdown, sold these manors by auction, which were purchased by the present proprietor, lord Carrington. The manor-house of Loakes, situated near the town, was considerably enlarged and improved by lord Shelburne, and the marquis of Lansdown bestowed much expence in laying out the gardens and pleasure-grounds. The house has been almost wholly rebuilt by the present noble owner, from the designs of James Wyatt: it is now called Wycombe-abbey. The parish-church of High Wycombe is mentioned by Warton as having been built in the reign of Henry II.: the present fabric is of much later date, and the tower was built in 1522. Between the aisle and the chancel is an ancient oak screen, which, by an inscription, appears to have been put up in 1460, at the expence of the Redhead family. In the chancel is a monument to Henry Petty, earl of Shelburne, who died in 1751. It was executed by Scheemakers, at the expence of 2000*l.*, which was bequeathed by his lordship for that purpose. In the south aisle is a very handsome monument by Carlini, for Sophia, countess of Shelburne, (first wife of the late marquis,) who died in 1791, with a female figure reclining on an urn. In the church are memorials of the families of Archdale, Lluelyn, Shrimpton, and Bradshaw. William Bradshaw, who died in 1614, was 103 years of age. In the church-yard is the tomb of Robert Williams, the late sexton, who died in 1793, at the age of 102. Two hospitals for lepers were founded in this town in the early part of the 13th century: one of them was granted by queen Elizabeth to the corporation; and the lands are now applied to the maintenance of a hospital or alms-house for poor people, and a grammar-school.

WYCOMBE, *West*, is a populous village and parish in the hundred of Desborough, situated about two miles N.W. by W. from High Wycombe, on the road to Oxford. It was anciently called Haverindon. The manor was from a remote period till the Reformation attached to the see of Winchester: the present proprietor is sir John Dashwood King, who has a seat here, named West Wycombe-house, which was built by sir Francis Dashwood, but was much enlarged,

enlarged, and furnished with a profusion of ornaments by his son lord Le Despencer. The parish-church stands on the summit of a steep hill, at a small distance from the village, within the site of an ancient circular intrenchment. It was rebuilt in 1763, (except the tower and chancel, which are parts of a more ancient structure,) by lord Le Despencer, who fitted it up in the Grecian style: the ceiling is painted with Mosaic ornaments. Near the east end of the church is an hexagonal building, erected by his lordship. One side of this building is inscribed to the memory of John, earl of Westmoreland, and another to George, baron of Melcombe Regis, whose legacy to lord Le Despencer, for the purpose of erecting a monument to his memory, was the cause of his lordship's building this singular mausoleum. Within it are several recesses for monuments, and niches for arms and busts. The population of this parish, in the return of the year 1811, is stated to be 1362; the number of houses 273.—Lyfons's *Magna Britannia*, vol. i. Buckinghamshire, 1806. *Beauties of England and Wales*, vol. i. Buckinghamshire, by J. Britton and E. W. Brayley, 1801.

WYDAW, a river of Denmark, which runs into the North sea, near Tondern, in the duchy of Sleswick.

WYDRAUGHT, a water-course, or water-passage, to carry off the filth and sullage of a house; properly a sink, or common-sewer.

WYE, in *Geography*, called by Leland, in his *Itinerary*, a "pratie market townlet," is now only a considerable village of the county of Kent, England, as its market has been long discontinued. In the *Domesday-book* it is written *Wi*, and by that appellation it was granted by the Conqueror to the abbey of Battle, in Suffex, which he had founded in remembrance of his victory over Harold, it having been previously a part of the demesne lands of the Saxon kings. "The *Chronicles of Battle abbey* affirm," says Lambard, "that there were sometime two-and-twenty hundredths subject to the jurisdiction of this manor." The extensive grant of the royal manor of Wye, with all its appendages, liberties, and royal customs, was confirmed to the abbey of Battle by different sovereigns, and it continued parcel of its possessions till the period of the dissolution. Queen Elizabeth, in her first year, granted it, together with various estates in the vicinity, to her kinsman, Henry Cary, lord Hunsdon, to hold *in capite* by knight's service. The church of this parish was made collegiate by archbishop Kemp, who was a native of the place, and is supposed to have rebuilt this edifice at the same time that he founded the adjoining college, in the year 1447. It consists of a nave, aisles, and chancel, with a large embattled tower at the south-east angle; the nave is separated from the aisles by four pointed arches on each side, rising from clustered columns; the chancel was rebuilt at the commencement of the last century, and has a semicircular east end.

The ancient college, now the grammar-school, founded by archbishop Kemp, stands on the east side of the church-yard. He endowed it for a provost and six fellows, "two of whom had an additional stipend for the duty of the church, and care of a grammar-school," in which all scholars, both rich and poor, were to be instructed gratis. Another school was instituted here about the year 1708, under a bequest of lady Joanna Thornhill, who, among other charities to the poor of Wye, directed that the residue of her estates should be applied to the instruction of their children. Sir George Wheeler added to this foundation, and gave the college as the residence for the master of the grammar-school, and for the master and mistress of lady Thornhill's school. The college buildings form a quad-

rangle, and the old hall is a large vaulted room, now used for the school. The population of this parish in the year 1811 consisted of 1322 persons, who occupied 224 houses. In this parish is Ollantigh, where archbishop Kemp was born in 1380, and where towards the end of his life he built a chapel, or oratory. Here also it is conjectured was born Thomas Kemp, bishop of London, and nephew of the archbishop. John Sawbridge, a patriotic alderman of London, was likewise a native of this place, where he was born March 17, 1732, and where he died in 1795. His sister, Mrs. Macaulay Graham, an English historian, derived her birth from this place on the 23d of March 1731. (See GRAHAM, MACAULAY.) About one mile N.E. from Ollantigh, a Roman burying-place was discovered in the year 1703, and several skeletons, urns, and other vestiges of interments, have been discovered, and are now preserved at Heppington, in this county.—Hasted's *History, &c. of Kent*, 12 vols. 8vo. *Beauties of England, &c. Kent*, by E. W. Brayley, 8vo. 1806.

WYE, a river of South Wales, is rendered particularly noted, in consequence of the high praises bestowed on it by topographers, tourists, and poets. The shores of this famed stream are distinguished by bold, rocky, and woody scenery, and adorned by several towns, seats, castles, and abbeys. The poet Gray says, "its banks are a succession of nameless beauties." Taking its source on the south side of the mountain called Plinlimmon, in Montgomeryshire, within a quarter of a mile from the spring-head of the river Severn, the river takes a course in general to the S.E. between the counties of Brecknock on the W. and Radnor on the E. Entering Herefordshire, it winds by and partly through the capital of that county; and then turning southward, it forms the boundary between Gloucestershire on the E. and Monmouthshire on the W., until it unites its stream with that of the Severn, a few miles below Chepstow. At its source, the scenery is wild, romantic, and bare; but after descending to Bualt, the scenes are extremely beautiful. In the valley of Glasbury, the stream is so considerable as to have required in 1783 a stone bridge of seven arches, which twelve years afterwards was swept away by the floods. At Hay, where it enters Herefordshire and receives the waters of the Dulas, the Wye is so much increased in the winter season as to be navigable for barges. From thence to Hereford it winds through a continuation of rich and beautiful scenes, and passes by many pleasant villages and country-seats. Bradwardine, a village, where in ancient times stood a castle, on the right or south bank, gave name to Thomas Bradwardine, archbishop of Canterbury, who was styled from the depth of his learning "the profound doctor." About three miles lower down is Moccas-court, the modern residence of sir George Cornwall, bart. About six miles below Hereford the Wye receives the Lug, one of the three principal rivers of the county, flowing in general south-east from the borders of Radnorshire. "Near the conflux of the Lux and Wye," says Camden, "to the east, a hill called Marclay-hill did, in the year 1575, rouse itself as it were out of sleep, and for three days together, shoving its prodigious body forward, with a horrible roaring noise, raised itself, to the great astonishment of all beholders, to a higher place." Two miles below the influx of the Lug, but on the west side of the Wye, is Holme-Lacy, the ancient seat of the Scudamores, the heirs of whom married the late duke of Norfolk. The mansion occupies the site of an abbey, which was founded in the time of Henry III. Five or six miles lower down, and on the same side of the Wye, is Harewood, a remnant of the forest of that name, selected by

by Maſon as the ſcene of his drama of *Elfrida*; for there Ethelwold, the confidante of king Edgar, had his caſtle, in which the fair *Elfrida* was concealed. Five miles farther down, on the eaſt bank of the river, is Roſs, conſecrated in the poetry of Pope by his fascinating deſcription of what could be and actually was accompliſhed by the “Man of Roſs,” with “five hundred pounds a year.” The memory of this worthy man, John Kyrle, is preſerved by a monument in the church of Roſs. On the weſt ſide of the river are the remains of Wilton caſtle, a Norman ſtructure, once the reſidence of the Greys. Following the courſe of the Wye on the weſt, on the ſummit of a bold promontory clothed with wood appear the lofty towers of Goodrich caſtle, of great antiquity; for in 1204 it was granted by king John to Marſhall, earl of Pembroke. The views from the caſtle are extenſive and highly intereſting. At Coldwell rocks the ſcenery of the Wye is peculiarly grand, the prominences are overhung with oaks and ſhrubs, and ſeparated by deep ſhadowy dells. From Symond’s-gate or Yat, the ſummit of a lofty hill, the ſpectator diſcovers a ſingularly grand view of the windings of the river, and its romantic banks. Soon afterwards, entering a ſhort way into Monmouthſhire, the Wye bathes the walls of the capital, near which is Troy-houſe, the ancient feat of the duke of Beaufort, and aſſuming a ſouthern direction, runs along the limit between that county and Glouceſterſhire. The courſe of the river, in the latter part of the range, is leſs irregular than that through Herefordſhire, but it is not leſs intereſting. About a mile diſtant from its eaſt bank, on an eminence, ſtands St. Briavel’s caſtle, once of great extent and great ſtrength, erected by Miles, earl of Hereford, in the reign of Henry I. Lower down the ſtream and on the weſt bank is the curious village of Llandogo, diſperſed among trees on the ſide of a hill. Proceeding down the river by an eaſy bending courſe, in the midſt of very pictureſque ſcenery, appear the dilapidated and highly pictureſque remains of Tintern abbey, at the opening of a valley on the weſt bank. This venerable ruin is apparently incloſed by ſteep hills and hanging woods, which are ſeparated by the broad ſtream in the bottom. Paſſing much ſcenery equally beautiful, the eaſt bank of the river preſents a ſcreen of rocks, called Thorn and Black Cliffs, to which the tide reaches, and afterwards marſhy lands appear on both ſides. Next appear the rocks belonging to the celebrated grounds of Piersfield. Theſe reſemble the projecting baſtions of a caſtle, and powerfully reverberate ſounds that ſtrike againſt them. A little lower down is the Lover’s Leap, a precipitous rock; and the next ſweep of the river brings before the eye the noble remains of the caſtle of Chepſtow, perched on the ſummit of a lofty perpendicular cliff, impending over the weſt ſide of the river. The ſituation of the caſtle and the town of Chepſtow is peculiarly pictureſque. The beauties of the ſcene are, in the opinion of Mr. Wyndham, “ſo excellent, that the moſt exact critic in landſcape would ſcarcely wiſh to alter a poſition in the aſſemblage of woods, cliffs, ruins, and water.” Chepſtow caſtle is undoubtedly ancient, and Roman-Britiſh bricks are diſcovered in the walls; but its foundation can be traced only to Fitzoſborne, earl of Hereford, who erected it for the defence of the poſſeſſions he received from William of Normandy. Notwithſtanding the height and rapidity of the tides at Chepſtow, a bridge has long been eſtabliſhed there acroſs the Wye. It was formerly conſtructed wholly of timber, but is now made of caſt-iron. Although the tide be ſenſibly perceived only about Tintern abbey, five miles above Chepſtow, yet the water riſes in the river at this town to a very extraordinary

height. Formerly not leſs than ſeventy feet, as it is aſſerted; but fifty-fix feet is the greateſt riſe obſerved during the laſt hundred years. The tide ſetting up the Briſtol channel from the Atlantic is, by the gradual contraction of its courſe, forced to ſwell up in a very uncommon manner; and its progrels is ſtill farther impeded by the advance of the land on the north of the entrance of the Wye, up which river, as well as more directly up the Severn, it ruſhes with peculiar force. In deſcending the Wye from Chepſtow, the high impending rocks have a very ſtriking effect. At the conflux with the Severn, three miles below the town, the eſtuary of the latter river appears, bounded by the diſtant hills of Glouceſterſhire and Somerſetſhire. The general character of the river Wye is thus repreſented by Mr. Coxe: “It is diſtinguiſhed by its ſerpentine courſe, the uniform breadth of its channel, and the ſcenery of its banks. In the navigable part from Hereford downwards, the banks for the moſt part riſe abruptly from the edge of the water, and are clothed with foreſts and broken cliffs. In ſome places they approach ſo near that the river occupies the whole intermediate ſpace, and nothing is ſeen but wood, rock, and water: in others they alternately recede, and the eye catches an occaſional glimpe of hamlets, ruins, and detached buildings, partly ſeated on the margin of the ſtream, and partly ſcattered on the riſing grounds. The general character of the ſcenery, however, is wildneſs and ſolitude: and if we except the populous diſtrict of Monmouth, no river perhaps flows for ſo long a courſe through a well-cultivated country, the banks of which exhibit ſo few habitations.” Large hoys fitted to navigate the Severn can, with the tide, aſcend the Wye to Brookſwear, a populous village midway between Monmouth and Chepſtow, where they receive from and transfer into ſmall craft the various commodities with which they are loaded. The Wye as well as the Severn furniſhes a conſiderable quantity of ſalmon.—*Beauties of England and Wales, North Wales*, by the Rev. J. Evans, 8vo. 1810. Ditto, *Monmouthſhire*, by J. Britton, 1808. *Historical Tour in Monmouthſhire*, by the Rev. William Coxe, 2 vols. 4to. 1801. *Observations on the River Wye*, by the Rev. William Gilpin, 8vo. 1789.

WYE, a river of England, which runs into the Derwent, near Bakewell.—Alſo, a river of Maryland, which runs into the Cheſapeak, N. lat. 38° 54'. W. long. 76° 20'.

WYENOKE, a town of Virginia.

WYERSDALE, NETHER, a townſhip in the hundred of Amounderneſs, county palatine of Lancaſter, England, is ſituated four miles N.N.E. from Garſlang, and was ſtated in the return of the year 1811 to contain a population of 713 perſons, occupying 145 houſes.

WYERSDALE, Over, a townſhip in the hundred of Lonſdale South of the Sands, Lancaſhire, England, is ſituated ſix miles N.N.E. from Garſlang, and in the year 1811 contained 154 houſes and 802 inhabitants. A colony of Ciſtercian monks were for ſome time fixed here, but about A.D. 1188 they removed into Ireland, and founded the abbey of Wythney.

WYERSDALE *Foreſt*. See LANCAſHIRE, *Foreſts in*.

WYFFLERS, in *Military Language*, ſubordinate officers in the Engliſh infantry, whole buſineſs, in the time of queen Elizabeth, appears to have been to drill the men, to inſtruct them how to carry their arms, and to arrange them according to their ranks in proper order.

WYFORDBY, or WYVERBY, in *Geography*, a ſmall pariſh in the hundred of Framland, county of Leiceſter, England, is ſituated three miles E. from Melton Mowbray; and in the population report of 1811 was returned as containing

taining 20 houses, and 97 inhabitants. It includes the hamlet of Brentingby.

WYGBYGERA, a town of Sweden, in Angermannland; 30 miles N. of Hernofand.

WYGELN, a high mountain of Norway.

WYHAM, a parish in the wapentake of Ludborough, in Lindsey division of the county of Lincoln, England, is situated 7 miles N.N.W. from Louth; and was stated in the year 1811 to have a population of 87, occupying 10 houses.

WYHOMICA, or WYHONIEC, a town of Lithuania; 20 miles N.N.E. of Pinsk.

WYK, a town of Sweden, in the province of Smaland; 65 miles N.N.W. of Calmar.

WYKA, a town of Sweden, in Dalecarlia; 14 miles S.E. of Fahlun.

WYKE, anciently denoted a farm, hamlet, or little village.

WYKE, in *Geography*, a tything in the parish of Worplesdon, hundred of Woking, county of Surrey, England, is situated 6 miles W. by N. from Guildford, and was returned in the year 1811 as containing 30 houses, and 125 inhabitants.

WYKE *Regis*, a parish in the hundred of the same name, in Dorchester division of the county of Dorset, England, is 2 miles W.S.W. from Weymouth. The population in the year 1811 was returned as 570, the number of houses as 134. The church, which is the mother-church to Melcombe Regis, is a spacious building, with a lofty tower, serving as a land-mark. From this village there is a ferry to Portland isle.

WYKE-Hamon, a parish in the hundred of Cleley, Northamptonshire, England. The church is in ruins. The population is included with that of the adjoining parish of Wykens, or Wyke Dyve.

WYKEHAM, in *Biography*. See WILLIAM of Wykeham.

WYKEHAM, or *Wycombe*, in *Geography*, a township in the hundred of East Goscote, county of Leicester, England; 5 miles N.E. by N. from Melton Mowbray. The population, including the adjoining township of Caldwell, was in 1811 stated to be 95, occupying 25 houses.

WYKEHAM, a township in the east division of the wapentake of Pickering Lythe, North Riding of the county of York, England, is 6 miles S.W. by W. from Scarborough; and in the year 1811 contained 87 houses, and 511 inhabitants. About the year 1153, Pain Fitz Osbert built and endowed a priory for Cistercian nuns at this place. At the dissolution there were nine religious persons in the house, with an estate of 25*l.* 17*s.* 6*d.* per annum. Henry VIII. granted the house to Francis Poole.

WYKEHAM, *East*, is a parish in the Wold division of Louth-Eske hundred, in Lindsey part of Lincolnshire, England, situated 7 miles N.W. by W. from Louth. The church is in ruins. The population was stated, in the return of the year 1811, to be 23, the number of houses 4.

WYKEHAM, *West*, is a parish in the east division of the wapentake of Wraggoc, in Lindsey division of Lincolnshire, England, adjoining to the foregoing. The church is also in ruins.

WYKEN, a parish in the county of the city of Coventry, Warwickshire, England, is 3 miles N.E. by E. from the city; and, according to the population return of the year 1811, contained 13 houses, and 72 inhabitants.

WYKENS, or WYKE-DYVE, a parish in the hundred of Cleley, county of Northampton, England, situated 7

miles S.E. by S. from Towcester, and 3 miles W.S.W. from Stony-Stratford; Bucks. This parish is united with that of Wyke-Hamon, and in 1811 the joint population was returned as 385, the number of houses as 57.

WYL. See WEYL.

WYLAM, a township in the parish of Ovingham, Tyne-dale-ward, county of Northumberland. In the year 1811 it contained 159 houses, and 795 inhabitants; 9 miles W. from Newcastle.

WYLDE, JOHN, in *Biography*, the author, or rather the compiler of a tract on music in the MS. of Waltham Holy Cross, now in the possession of the marquis of Lansdown, entitled "Musica Guidonis Monachi." It is the first in the volume, but not written by Guido, as the title seems to imply, but an explanation of his principles; it is divided into two books, and appears to have been compiled by the precentor of Waltham abbey, John Wylde, pr. "Quia juxta Sapientissimum Salomonem dura est." The author does not confine himself to the doctrines of Guido, but cites later writers. The basis of the tract, however, is the *Misero-logus*, and his other writings, in which he treats of the monochord, the scale, the harmonic hand, the explanation of which he calls *manual music*, ecclesiastical tones, solmification, clefs, with a battle between B flat and B natural, are the subjects of the first book, consisting of twenty-two chapters.

The second book, or distinction, contains thirty-one chapters. In the first he speaks of a Guido Minor, surnamed *Augensis*, as a writer on the ecclesiastical chant. He had mentioned this author in the seventh chapter of the first book; but who he was, or when he lived, we are unable to discover. It seems, however, as if some such musical writer had existed, and that his name, by the ignorance or inattention of the scribes of ancient MSS., had been confounded with that of Guido d'Arezzo.

In several of the succeeding chapters he treats of intervals and their species, offering nothing new or singular, except where he draws a parallel between the tone and semitone, and Leah and Rachel, Jacob's wives, which, it is presumed, will excite no great curiosity in our readers.

Attention is engaged, however, in the tenth chapter, by a "Cantilena," as the author calls it, of the Great Guido. It is a kind of *solfe-ggio*, or exercise for the voice, through all the intervals, which is only rendered valuable, perhaps, by the supposition of its having been produced by the celebrated author of the musical alphabet. See SERRA.

WYLIA, in *Botany*, another new umbelliferous genus of professor Hoffmann's, (see WENDIA,) dedicated by its author to Dr. J. Wylie, privy counsellor to the emperor of Russia, inspector of medicine and surgery in the Russian army, &c. &c., author of a *Pharmacopœia Castrensis Ruthena*, in which his highly commendable aim has been to indicate the medical properties, and to fix the names of the native plants of Russia.—Hoffm. Gen. Plant. Umbellif. v. 1. 3. t. 2.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellatae*, Linn. *Umbellifera*, Juss.

Gen. Ch. *General Involucrum* of one ovato-lanceolate, membranous, half-clasping leaf, fringed with hairs; *partial* of five ovate, nearly entire, concave, two or three-ribbed leaves, bordered with a pellucid fringed membrane. *Petioles* of five minute teeth, permanent. *Cor.* universal irregular; flowers of the disk perfect, fertile, as well as the female ones which form the radius; some male flowers are either interperfed in the disk, or disposed in separate umbels: *partial* of five petals; unequal in the flowers of the radius, the outermost very large, either obovate and flattened,

tened, or inverfely heart-shaped, with a long claw; equal in thofe of the difk. *Stam.* Filaments five, thread-shaped, at firft inflexed, and concealed in the hollows of the petals, afterwards prominent; anthers roundifh. *Pift.* Germen ovate-oblong, more or lefs tapering; ftyles erect, thread-shaped, nearly equal, ftanding on a cup-shaped bafe; ftigmas fimple. *Peric.* Fruit linear-oblong, beaked, fomewhat compressed, crowned with the erect, permanent ftyles, and their cup-like, flightly notched bafis. *Seeds* two, linear-oblong, bifpid, ftriated, the ribs elevated, continued into the beak with intermediate furrows; valves of the beak parallel to the fruit.

Eff. Ch. General and partial involuclral leaves ovate. Flowers polygamous, radiant. Calyx five-toothed. *Fruit* oblong, fomewhat compressed, beaked; valves of the beak parallel to the fruit.

Obf. The chief differences which have led professor Hoffmann to feparate this genus from SCANDIX, (fee that article,) appear to be the nearly entire leaves of the partial involuclrum, which are lacinated in *Scandix*; the radiant corolla, and, as he fays, the valves of the beak being parallel, not contrary to the fruit; that is, as we prefume, compressed in a contrary direction in one genus to what they are in the other. For this we rely on the learned and judicious author not having materials fufficient to verify his obfervation. We muft remark, that the involuclral leaves in *Wylia*, though not lacinated, have a notch or two at the end, and precifely accord in texture with thofe of *Scandix*. Many of the umbels in this genus are fimple, or occasionally two or three together, refembling a compound umbel.

1. *W. australis.* Southern *Wylia*. Hoffm. n. 1. t. 2. f. 1. (*Scandix australis*; Linn. Sp. Pl. 369. Sm. Fl. Græc. Sibth. t. 285, unpubl. See SCANDIX n. 6.)—Umbels fimple, or in pairs, of few flowers. Radiant petals obovate, nearly entire. Beak of the fruit almoft ftraight.—Native of fields in Italy and the Levant, as well as in Tauria, about Sudak, flowering in May. *Root* annual. *Herb* fender. *Stem* round, fometimes quite fmooth, fometimes more or lefs hairy. *Leaves* triply pinnate, with linear acute fegments, and hairy, or rather fringed *footstalks*. *Umbels* final and dense, on long ftalks; the lower ones oppofite to the leaves, folitary and fimple; upper in pairs, rarely three together, and even in that cafe not conftituting a real compound umbel, as an examination of fpecimens will readily fhew. *Flowers* white, moderately radiant. *Largelt petals* fometimes flightly emarginate. *Fruits* from fix to ten perfected in each umbel, their beaks nearly or quite ftraight, quadrangular, rough with fhort erect briftles.

2. *W. radians.* Radiating *Wylia*. Hoffm. n. 2. t. 2. f. 2. (*Scandix australis* β; Marfch. Taur.-Caucas. v. 1. 424. S. falcata; Londe Journ. de la Soc. des Natural. de Mofcou, for 1806, 57. t. 5.)—Umbels aggregate, from two to five, many-flowered. Radiant petals elongated, wavy. Beak of the fruit incurved.—Frequent in Tauria, flowering in May. This is confidered by the authors who have defcribed it as about equally related to the foregoing and to the *grandiflora*. We have no other guide than a beautiful engraving, copied by Hoffmann from the figure above cited, with the addition of the magnified and diflected fructification. By this it appears that the partial umbels are rather more numerous affembled, making more apparently compound umbels. The *flowers* are more confpicuoufly radiant. *Fruits* more numerous in each umbel, from twelve to twenty, with ftrongly incurved rough beaks. We confeff ourfelves unable to determine thefe two fpecies clearly by

the fpecific differences of professor Hoffmann, which we fubjoin for the fatisfaction of our readers.

W. australis, caule petiolifque hirtutis, corollis petalifque radiantibus obovatis integris.

W. radians, caule petiolifque pilofis, umbellis glabris, corollis petalis fructibusque radiantibus.

The hairinefs is evidently variable, and the other characters, perhaps from fome typographical error, do not contraft with each other.

3. *W. grandiflora.* Large-flowered *Wylia*. Hoffm. n. 3. t. 2. f. 3. (*Scandix grandiflora*; Linn. Sp. Pl. 369; fee SCANDIX n. 10. Marfch. Taur.-Caucas. v. 1. 230.)—General umbels of from three to five very hairy rays. Radiant petals flightly emarginate.—Native of fields in Tartary and Georgia, flowering in May and June. Having difcovered a fpecimen of this in our collection fince the article SCANDIX was written, we are enabled to compare it with the defcriptions of authors, and to felect the following particulars:—The *root* is annual, tapering. *Stem* about a foot high, round, purplifh, flightly branched, quite fmooth in our fpecimen; Hoffmann fays clothed with long hairs. *Leaves* much like the laft; their *footstalks* fomewhat hairy. *Umbels* terminal; the *general* ones fometimes on fhort ftalks, each compofed of from three to five long, fender, coarfely and abundantly hairy rays, with a leafy, fimple or divided, linear leaf, in the place of a general involuclrum. *Partial umbels* of numerous fhort fmooth rays; their *involuclrum* of fveral, moftly double-pointed, ovate, white-edged, fringed leaves. *Flowers* remarkably radiant; their *largelt petals* obovate, not always emarginate, each furnifhed with a long claw. Beak of the *fruit* rather fealy, as Hoffmann delineates it, than hairy. His figures, in this and the other fpecies, except *radians*, exhibit the parts of fructification only.

4. *W. iberica.* Georgian *Wylia*. Hoffm. n. 4. t. 2. f. 4. (*Scandix iberica*; Marfch. Taur.-Caucas. v. 1. 425. S. falcata; ibid. 230, excluding the fynonym.)—General umbels of four or five very fmooth rays. Radiant petals emarginate, with an inflexed point. *Stem* fomewhat hairy at one fide.—Native of Georgia. Annual. Very nearly related to the laft in habit and fize. The *ftem* is, as in that, fometimes quite fmooth. The rays of both general and partial umbels are faid to be always very fmooth. Radiant petals of a fmall proportion, and, as it feems to us, effentially diftinguifhed by their fhort inflexed points. The beak of the *fruit* is defcribed as marked with two hairy lines, and not hairy in every direction. We have feen no fpecimen.

WYLSTER, in *Geography*. See WILSTER.

WYMERING, a parifh in the hundred of Portfdown, Hampfhire, England, returned in the year 1811 as containing 121 houfes, and 740 inhabitants; 4 miles W. from Havant.

WYMINGTON, or WIMMINGTON, a parifh in the hundred of Willey, county of Bedford, England, is fituated 12 miles N.W. by N. from the county town, and about 3 miles from Higham Ferrers, Northamptonfhire. Wymington church, a fine ftructure, was built by John Curteys, then lord of the manor, and mayor of the ftaple at Calais, who died in 1391, as appears from an infcription on his tomb. The braffes of himfelf and his wife are on a flab of black marble under canopies, and are well preferved. The population of the parifh, in the return of 1811, was ftated to be 235, the number of houfes 40.

WYMOA BAY, a bay on the S. coaft of Atooi, one of the Sandwich iflands. N. lat. 21° 57'. E. long. 200° 20'.

WYMONDHAM, or WINDHAM, a market-town in the hundred

hundred of Forehoe, and county of Norfolk, England, is situated 9 miles W.S.W. from Norwich, on the great road to London, from which it is distant 100 miles N.E. by E. This place has been supposed to be of Roman origin; and some writers have considered it as the Sitomagus of the Itinerary, though there are not the smallest traces to support that opinion. The name is purely Saxon; and the consequence of the town arose from the erection of a monastery here in the time of Henry I. A.D. 1130, by William de Albini, who amply endowed it with lands, which were confirmed with additions and privileges annexed by the reigning monarch. From the register of St. Alban's, this religious house appears to have been originally founded as a cell for black monks of the Augustine order; and its annual revenues at the dissolution amounted, according to Dugdale, to 211*l.* 16*s.* 6*d.* By the inquisition made at that period, the monastery was found in a regular state; and the abbot and monks in general were declared to have led blameless lives. The abbey-church was a large, handsome, cruciform building, erected soon after the year 1130. It consisted of a choir, nave, transept, north and south aisles, with a tower standing in the centre, still called the abbey-teeple, and another at the west end. When the monastery was destroyed, the south aisle, over which were lodgings for supernumerary monks, was demolished: but the king granted the inhabitants leave to build another. Anxious to preserve their noble church, they also obtained the following parts, which had been condemned by the act for removing superstitious buildings:—The abbey, teeple, vestry, monks' lodgings over the south aisle, St. Margaret's chapel, the chapel of the Blessed Virgin, the chapel of St. Thomas à Becket, and the choir. These were granted on condition that the inhabitants paid the king for the lead at the rate of 4*l.* per fodder, of twenty-four square feet.

The present church consists of a nave with aisles, a large western tower, and another at the intersection of the nave with the transepts. The ancient parts of the building display semicircular arches with short columns, large piers, &c. which appear to be parts of the original structure. At the east end, and on the south side of the porch, are some fragments of walls. The north aisle, porch, and towers, are of a much later style than the nave and south aisle. The church is curious, and highly interesting to the architectural antiquary and draughtsman. In it is a large font, ornamented with bold sculpture, and raised on steps. The remains of the founder were interred in the choir in 1156. The families of Albini, earls of Arundel, of Knevet, and of Clifton, are deposited in this church. Several guilds were founded here, the revenues of which have been appropriated to other purposes. Wymondham parish is extensive, and comprehends several hamlets, which are called the outfoken division, whilst the town is divided into several parts called the infoken division. Many of the inhabitants are employed in various branches of weaving. The distinguished family of Wyndham, or Windham, derives its name from this place.

North of the town is Kimberly-hall, the seat of lord Wodehouse. The house is seated in an extensive and beautiful park, which contains a fine piece of water, and some noble masses of forest-trees. In the house is a portrait of Vanduyck, by himself, when a young man.—Blomefield's History, &c. of Norfolk, 11 vols. 8vo. Beauties of England, Norfolk; by J. Britton, 8vo. 1809.

WYMONDHAM, a parish in the hundred of Framland, county of Leicester, England, situated 6 miles E. from Melton Mowbray, and 104 miles N.N.W. from London.

VOL. XXXVIII.

It is very ancient, and was formerly furrounded with walls: the inhabitants still possess an exemption originally granted to the duchy of Lancaster. In the return of the year 1811, the population was stated to be 437, occupying 81 houses.

WYMONDLEY, or WYMONDESLEY, *Great*, a parish in the hundred of Brinkwater, county of Hertford, England, situated within three miles E.S.E. from Hitchin. The manor was given by William the Conqueror to a noble Norman, named Fitz-beck, by the service of grand sergentry; that the lords of the said manor should present to the kings of England the first cup of drink at dinner on the day of their coronation: the cup becoming the property of the said lords. This service has continued with the manor: lieutenant-colonel Cracherood performed the office of cup-bearer at the coronation of George III. The population of the parish was, in the return of 1811, stated to be 212, and the number of houses 46.—*Beauties of England and Wales*, vol. vii. Hertfordshire, by E. W. Brayley.

WYMONDLEY, or *Wymondesley, Little*, is also a parish in the same hundred, adjoining to Great Wymondley, and containing, in the year 1811, 34 houses, and 188 inhabitants. A priory of Austin canons was founded here by Richard de Augustine, in the time of Henry III.: the site was granted to James Needham, gent., clerk of the king's works, in whose descendants it continued till the death of George Needham, esq. in 1726. It was then sold to Samuel Vanderplank, esq., and was lately the property of Christopher Clitherowlsy, who married Mr. Vanderplank's granddaughter.

Wymondley-house, in this vicinity, formerly the residence of a private gentleman, is now an academy for the education of Protestant Dissenting ministers. This institution originated at Northampton in 1729, by the endowment of William Coward, esq. a West India merchant. The celebrated Dr. Doddridge was the first tutor, which office he held twenty-two years. In 1752 the academy was removed to Daventry, and thence back to Northampton; and finally in 1799 to this place, having been previously united with an academy in London, under the successive tuition of Mr. Eames, F.R.S., Dr. Jennings, Dr. Savage, Dr. Kippis, and Dr. Rees, supported by the same fund, and unfortunately for the interests of literature and science discontinued. The library contains a valuable assemblage of upwards of 10,000 volumes of the best authors in divinity, criticism, classics, mathematics, topographical antiquities, &c. with a cabinet of medals, a collection of natural history, and other curiosities. This valuable library consists principally of a rich collection of books, bequeathed by the late Rev. Mr. Miles, F.R.S., and appropriated to the London Academy, and augmented by numerous purchases.—*Beauties of England and Wales*, vol. vii. by E. W. Brayley. And Private Information.

WYNANTS, JOHN, in *Biography*, an able and eminent landscape-painter, born at Haerlem in 1600. Whether he were his own instructor or not does not appear, or how he qualified himself to attain that station among the artists of his country which he so justly holds. His pictures are taken from the simple scenes of nature which surrounded his birth-place, and which he has represented with great vivacity and reality, though they sometimes are overcharged in their contrasts of colouring. A sandy bank, with broken patches of grass and plants, with stunted trees beside it, and a winding road passing over the bank, presents from his pencil an agreeable and interesting effect. Sometimes we find the entrance of a wood, with a cottage or lovel

beside

beside it, treated by him with great attention to the varied effect of colour in nature, and a dexterous management of chiaro-oscuro; and always with the most free and skilful touch, though generally upon a small scale. As he painted with facility, his works are not rare, though they bear a good price when in perfect preservation. Wynants established an academy, which produced many excellent painters. Among others of great celebrity, were Adriaan Vanderveelde and Philip Wouwermans, both of whom occasionally embellished their master's pictures with figures. He died in 1670, aged 70. He left numerous beautiful etchings of landscapes.

WYNNE, *Mrs.* CASSANDRA FREDERICA, the finest harpsichord player of her time. She was the daughter of signora Pompeati, the second female singer in Gluck's opera of "La Caduta de Giganti," performed in 1746, on the suppression of the rebellion; but though she nominally performed the part of second woman, she acted and sung in so masculine and violent a manner, that no female symptoms were discoverable. But this lady was better known afterwards by the name of Madame Cornellys, whose concerts, *ridottas*, assemblies, and masquerades, in Soho-square, were the gaiest and most fashionable amusements in London during many years.

The little Frederica, daughter of the Pompeati, was an élève of Paradie's, (some say his daughter,) and the first early player, the neatest, and the best which had ever appeared in our country during infancy, performing at six years old, with the utmost precision and firmness, propped up by cushions, the whole book of her master's twelve excellent lessons, probably composed expressly as progressive exercises for her use, with many lessons by Scarlatti and Alberti.

In 1769, when grown up, she went into Italy, where she was the wonder and subject of elege in that mother and seat of arts. We have often heard her perform at different periods of her life, and continued to think her improved to the last.

WYNNE, ———, esq., a Yorkshire gentleman, one of the best dilettanti performers on the violin that we have heard. He was a man of fortune, and of an ancient family. To gratify his passion for music, he went into Italy early in life, where he married, and remained in different great cities till he had almost totally forgotten his mother-tongue. He likewise travelled through Germany, and having two daughters, he had always a music-master on his establishment, not only to instruct them, but to accompany himself. When he was last in England, he had Pfeifer with him for these purposes, a worthy German, and an excellent musician and performer on several instruments, who died in London of a consumption.

Besides being a good performer on the violin, Mr. Wynne had studied composition sufficiently to compose trios, which were far above the common run of trios at that time in point of taste and invention, and well put together.

WYNSBACH, in *Geography*, a town of Austria; 4 miles E. of Schwannastatt.

WYNSTER. See WINSTER.

WYOMING, a settlement and fort on the river Susquehanna. In the year 1778, this fort was attacked by a party of British and Indians. The garrison were soon overpowered, and fell a prey to Indian barbarity; after a bloody military execution of a great part, the rest were shut up in the barracks, to which they set fire, and consumed the whole; 2 miles above Wilkesbarre.

WYONOKE CREEK, a river of North Carolina, which runs into the sea, N. lat. 36° 30'.

WYRARDSBURY, or WRAYSEBURY, a parish in the hundred of Stoke, and county of Buckingham, England, is situated near the banks of the Thames, 3 miles S.W. from Colnebrooke, and 3 miles N.W. from Staines, Middlesex. The manor belonged to the priory of Ankerwyke, in the same parish, which was founded in the reign of Henry II. for Benedictine nuns by Gilbert de Montfichet and his son Richard. In 1538 the priory was given to Bisham abbey, and after the dissolution it was granted to lord Windsor. Having afterwards reverted to the crown in exchange, it was given by Edward VI. in 1540 to sir Thomas Smith, the celebrated statesman, who resided at Ankerwyke. It was afterwards for many years the seat of the Salter family, of whom it was purchased by the Lees; and by marriage with an heiress came into the possession of sir Philip Harcourt, ancestor of the present proprietor, John Simon Harcourt, esq. There are no remains of the conventual buildings. Soon after the dissolution a mansion was built on the site by lord Windsor, or sir Thomas Smith: the hall of this mansion still remains. Near the house is a remarkably large yew-tree, which at six feet from the ground measures thirty feet five inches in girth. In the parish-church are monuments of the Harcourt family; and also of Thomas Wright, esq. and Thomas Gill, esq. aldermen of London, who died within a fortnight of each other in the year 1798. The population return of the year 1811 states this parish to contain 120 houses, and 560 inhabitants. The parish was inclosed by an act of parliament passed in the year 1799: a parcel of the waste was allotted for the purpose of holding a fair on the Friday in Whitsun week, pursuant to ancient custom.—Lysons's *Magna Britannia*, vol. i. Buckinghamshire.

WYRE, a river of Lancashire, which runs into the Irish sea, 9 miles W. of Garstang. N. lat. 53° 53'. W. long. 2° 56'.—Also, a river of France, which joins the Semoy, 3 miles E. of Chiny.

WYRIL POINT, a cape of England, on the coast of Durham. N. lat. 55° 3'.

WYSAUKING CREEK, a river of Pennsylvania, which runs into the E. branch of the Susquehanna, N. lat. 41° 46'. W. long. 76° 27'.

WYSOCKS, a township of Pennsylvania, in the county of Luzerne, containing 619 inhabitants.

WYSOKIE, a town of Lithuania, in the palatinate of Brzesk; 16 miles N. of Brzesk.

WYSTIEZE, a town of Lithuania, in the palatinate of Brzesk; 8 miles N.E. of Brzesk.

WYSZOCK, a town of Lithuania, in the palatinate of Brzesk; 44 miles S.E. of Pinsk.

WYTA, or WITA *Plena*, signified a forfeiture of a hundred and twenty shillings. "Si pundbreche fiat in curia regis, plena wita sit; alibi, quinque marcae."

To swear according to the wyte, *secundum wita[m] jurare*, was to purge one's self by the oaths of so many witnesses, as the nature of the crime, and the punishment, or wyte, did require.

Hence, also, *bloodwite*, *legerwite*, *ferdwite*, *childwite*, *wardwite*, &c. See *Ferd-Wite*, *Child-Wite*, &c.

WYTE, WYTA, or WITE, WITA, in our *Ancient Customs*, a pecuniary penalty, or mulct.

"Jurat secundum wita[m], quod nec fuerat furti conscius, nec coadjutor in eo." Leg. Inæ.

The Saxons had two kinds of punishments, *were* and *wyte*; the first for the more grievous offences.

W Y T

The *wyt* was for the less heinous ones. It was not fixed to any certain sum; but left at liberty, to be varied according to the case.

Hence also *wyte*, or *wittree*, one of the terms of privilege granted our sportsmen; signifying a freedom or immunity from fines or amerciaments: or, as it is vulgarly conceived, from being liable to be begged for fools, for lack of wit.

WYTHE, in *Law*, the same as waif.

W Z E

WYTHE, in *Geography*, a county of Virginia, between the river Kanhawa and North Carolina, with 8356 inhabitants, including 1157 slaves.

WYTHERS. See WITHERS.

WYTOOTACKEE, in *Geography*, an island in the South Pacific ocean, about 10 miles in circumference; discovered by captain Bligh in 1789. S. lat. 18° 52'. E. long. 200° 19'.

WZETIN. See USETIN.
